SMALL TRANSIT VEHICLES
STATE-OF-THE-ART OVERVIEW
AUGUST 1981

TECHNOLOGY SHARING IS A PROGRAM OF THE UNITED STATES DEPARTMENT OF TRANSPORTATION
FOREWORD

As part of its ongoing commitment to the principle of technology sharing, the U.S. Department of Transportation has initiated a series of publications based on research-and-development efforts sponsored by the Department. The series is comprised of technical reports, state-of-the-art documents, newsletters and bulletins, manuals and handbooks, bibliographies, and other special publications. All share a primary objective — to contribute to a better base of knowledge and understanding throughout the transportation community, and thereby, to improve the basis for decision-making within the community.

This document presents both an update and expansion of a 1975 Technology Sharing document which profiled small transit vehicles. This document presents information on the vehicles available and on the selection, procurement, and operational considerations of using small transit vehicles in a transportation service.

The information contained in this document is drawn from over 100 sources including conversations with transportation system operators, state and local planners, and vehicle suppliers. It is intended to be used as a guide to assist providers of transportation services, and community and state planners, in the selection and use of small transit vehicles. Included in this document is supplementary material serving as a sourcebook for further information.
ACKNOWLEDGMENTS

This report is jointly sponsored by the following organizations:

- OFFICE OF THE SECRETARY
  Office of Assistant Secretary for Governmental Affairs

- TRANSPORTATION SYSTEMS CENTER
  Technology Sharing Program Office

- URBAN MASS TRANSPORTATION ADMINISTRATION
  Associate Administrator for Technology Development and Deployment

A special acknowledgment is made to the many State and local government transportation officials who participated in the process and made this document the product of a true Federal, State, and local government partnership.

what are small transit vehicles?

IN RECENT YEARS, there has been a growth of transportation services offering an alternative to the scheduled, fixed-route services available in urban areas. In addition, public transportation services are beginning to appear more often in nonurban areas. These developments have increased the need for vehicles other than the standard 40-foot transit bus. Small transit vehicles have lower seating capacities, greater maneuverability, and capital costs which are within the financial capabilities of the operators of these new services.

This report is a state of the art of small transit vehicles. It provides an informational overview directed toward new or future service planners and operators of small vehicles. This report describes:

- The vehicles available and the considerations involved in their selection (Chapter II)
- Alternative procurement processes, concentrating on purchasing through the use of a bid process (Chapter III)
- Financial and operational considerations, including costs, maintenance, driver training, and insurance (Chapter IV)

However, it should be pointed out that the state of the art is constantly evolving as the available vehicles, and the uses to which they are put, evolve. Much of the existing information, unfortunately, is generally not available in journal articles nor in reports, but is rather in the minds of those who have had experience using small transit vehicles. Therefore, once the reader has reviewed this state-of-the-art document, it is recommended that he contact experienced operators to further increase his knowledge of the successful use of small transit vehicles.
The expression "small transit vehicle" generally refers to a vehicle smaller than the 40-foot standard transit bus; this is its meaning in this document. However, within the group of small transit vehicles there are a number of different types and sizes. The terms used for the subgroups of small transit vehicles are not standard. This report discusses the vehicles in groups according to their method of construction. (See Figure 1.) These are:

Figure 1. Types of Vehicles

- Standard Van
- Modified Van
- Body on Chassis
- Small Bus
• Standard van — the vans available from automotive manufacturers
• Modified van — standard vans with some body and/or chassis modification; available from the modifier
• Body on chassis — a "marriage" of a light truck chassis and a body, available from the body manufacturer
• Small bus — a bus whose chassis and body are designed as an integral unit durable in transit service; available from the small bus manufacturer.

These vehicles are described further in Chapter III. Chapter III also briefly discusses other vehicles, such as school buses which are currently used in transportation services.

---

**service roles of small transit vehicles**

**SMALL TRANSIT VEHICLES** are currently being used in a variety of transportation services:

• **Fixed-route services** with regular routes and schedules. Small urban and rural areas usually do not have ridership levels warranting the use of a regular transit bus commonly used in urban fixed-route services.

• **Shuttle services** which operate along heavily traveled corridors such as those in urban centers, large commercial mall areas, and airports.

• **Feeder services** which provide transportation to and from a regular transit route.

• **Demand-responsive services** which are characterized by flexible routing and scheduling to provide shared occupancy on demand, often with door-to-door service. Demand-responsive services are often provided for people whose mobility is limited due to age, or physical, mental, or emotional disabilities.

• **Pre-arranged ride-sharing services** which include van pooling and subscription buses that operate mainly during peak times to provide commuters who have predetermined work schedules the opportunity to share vehicles. These services are also provided by human service agencies for their own clients.

---

**advantages in using small transit vehicles**

There are several reasons small transit vehicles are better suited than standard transit buses for use in the services listed above.
MANEUVERABILITY. A study of transportation services using small vehicles found maneuverability to be a major factor in the decision to buy small vehicles (84). In many cases, because of street structure and local terrain, maneuverability is of prime importance. Small vehicles, because of their shorter turning radii, can maneuver more easily on narrow roads and around sharp corners. Limited curb space for stops is less of a problem with small vehicles (89). Additionally, some transit services require vehicles to drive into driveways and to back out; this is facilitated with small vehicles.

Small vehicles are also easier to drive; this has the advantage of increasing the availability of eligible drivers and decreasing the training needs. In addition, depending on state law, licensing requirements for drivers of small vehicles may not be as strict as those for drivers of large vehicles.

COST. In a cost comparison between vehicles of different sizes it is possible to distinguish between the capital costs (costs of buying the vehicle) and the operating costs (costs of running the vehicle).

1. Capital Costs
   Although the initial cost of a small vehicle is usually lower, it is not always true that the annual costs are substantially lower. Given the shorter life span of a smaller vehicle, the annual capital cost (including depreciation and finance costs) over the life of a smaller vehicle may not vary from larger vehicles (34).

2. Operating Costs
   The major components of operating costs are drivers' wages, fuel, and maintenance.

   Drivers' wages may or may not be affected by the size of a vehicle, despite the fact that drivers of small vehicles may not require the same driving skills as drivers of large vehicles. If a large number of small vehicles is used to meet the demand that fewer large vehicles could meet, additional drivers may be required.

   In considering fuel costs, it should be noted that small vehicles generally achieve a higher number of miles per gallon than large vehicles. However, most small vehicles use gasoline which is priced higher than the diesel fuel used by large vehicles.

   A survey of bus transit operations found that although maintenance costs for small vehicles may be lower on the average, the size of the operation ultimately determines the impact of lower maintenance costs of small vehicles (84). A small transit operation can avoid a large maintenance facility outlay by contracting out for

*Numbers in parentheses refer to References.*
service. If the vehicle is a standard van or has a mass-produced chassis, parts and service may not be difficult to obtain. However, some of the larger operations surveyed feel that small vehicle maintenance costs are higher because the addition of small vehicles requires a larger parts inventory, special facilities, and mechanic retraining. As a result, these large operations claim that repair costs per service mile for small vehicles are higher than those for standard-size buses.

3. Total Costs

However, when examining total costs, it is instructive to look at a 1977 study of fixed-route rural transportation in the Northeast and Mid-Atlantic regions which determined typical costs per vehicle kilometer. (See Figure 2.) From this figure it can be concluded that, with the exception of school buses, capital and operating costs increase as vehicle size increases. However, the findings also indicate that as vehicle size increases, costs per seat kilometer decrease. Therefore, it is most cost effective to use a vehicle whose capacity corresponds to the ridership level. In other words, when passenger demand is low, or the routing or scheduling of a service is such that a large number of passengers cannot be accommodated at one time, a small vehicle is more cost effective than a large vehicle.

RESIDENTIAL PREFERENCE. In residential areas, small vehicles may be preferred. Large transit buses are generally noisier, because they have diesel engines. (However, local sentiment with respect to size, noise, the impact on real estate values, etc., varies with the locality.) In addition, small transit-vehicle operations may attract passengers who have negative feelings towards large transit buses.

The small vehicle market is characterized by fragmented, low, and uncertain demand. The supply side of the market is in constant flux because suppliers are constantly entering and leaving the market.

As mentioned earlier, there are a number of service roles for small transit vehicles and, thus, there are a variety of different users for small vehicles. These users request vehicles tailored to their own services and clients, and they often place small orders. The uncertainty of demand stems primarily from the vehicle users' reliance on outside sources of funds. For example, with Federal funding sources it is difficult to predict:

- The continuation of funding programs
- Which transportation systems will receive funding
- The amount of time between a system's application and its approval

• Whether Federal regulations will delay the funding process. (For example Section 13(c) the Urban Mass Transportation Act of 1964, as amended, requires written assurance by the grant recipient that the interests of employees affected by such assistance will be protected. Obtaining employee approval of these assurances may require months of negotiations which could delay the ordering of vehicles.)

The variety of suppliers includes manufacturers of school buses, mobile homes, recreational vehicles, and other transit vehicles. They often use the same chassis utilized in their standard production line, but with bodies designed for transit service. The rapid movement of suppliers in and out of the market has made it difficult for buyers to identify sellers and to feel secure that a seller will stay in business long enough to honor warranty agreements and to ensure future parts availability. In addition, since many small vehicles have been in use only a short time, operators are not as familiar with the performance characteristics of these vehicles. Some of the vehicles which were in operation for several years are no longer being manufactured. (For example, of the 16 small transit vehicles profiled in a report written by this office in 1975, 13 are no longer manufactured.) In those cases, the manufacturers have either gone out of business, stopped producing small vehicles, or developed a different model.

Small buses, the largest type of vehicle discussed in this report, are relatively new and represent an attempt to combine the durability of a standard transit bus with the advantages of a small vehicle. However, unlike small buses, the standard and modified vans and body-on-chassis vehicles are not designed for the operating demands of transit service. Van chassis and the light truck chassis used for body-on-chassis vehicles are designed more for private use. This need for durable small transit vehicles has been discussed for the past few years. Durability was one of the issues addressed at a workshop on small buses held in 1978.

One of the conclusions of this workshop was that development time for a durable small bus could range from nearly four years for an integrated design to less than three years for a body-on-chassis small bus. The cost of developing a new small bus could range from $1 million for a bus chassis to more than $10 million for a sophisticated integrated design. Tooling for either small bus could cost several million more, depending on the number of new components required and on the assembly techniques.

In 1977, the Urban Mass Transportation Administration (UMTA) sponsored a study to design a 24- and a 26-foot heavy duty bus chassis. The development of a chassis, rather than of an integrated bus was preferred, given the limited market for a small bus and the higher costs of an integrated bus. It was hoped that a
chassis produced by two or three manufacturers would enable body manufacturers to produce a wider choice of buses than would be possible with the development of the integrated bus. Developing a bus body is less costly than developing a chassis, especially when the body is designed to be mounted on a chassis. However, at the time, none of the manufacturers shown the design were willing or able to produce the chassis.

A workshop held by the Transportation Research Board in 1979 estimated the national market for small transit vehicles to be from 5,000 to 10,000 units a year (41). The workshop participants felt that without a more supportive national policy to increase demand, their demand estimate was too low to encourage larger-scale production.
Figure 3. Factors Affecting Vehicle Selection

- Service Requirements (e.g., ridership level, clientele profile, routes & schedules)
- Operating Environment (e.g., climate, terrain, street structure)
- Maintenance and Storage Capabilities
- Financial Capabilities
- Other Factors (e.g., government regulations, insurance, political environment)
II SELECTION

THIS CHAPTER CONTAINS a description of the vehicle types and a list of major vehicle components; these vehicle types and components are discussed in terms of the operating data available. There is no discussion of specific vehicle makes for which performance data is so limited that no conclusions can be drawn. However, Appendixes A and B contain a list of manufacturers of small transit vehicles, of wheelchair lifts and ramps, and of wheelchair securements. The discussion of vehicle components is general and deals with small transit vehicles as a group.

With the exception of standard vans, small transit vehicles are made to order. Therefore, a system operator ordering a vehicle can specify that certain aspects of the vehicle be tailored to the system's requirements. For example, passenger accessibility may be a major requirement. Because many small transit vehicles are used in the transport of elderly and handicapped people, and because the U.S. Department of Transportation (DOT) is committed by law (the National Rehabilitation Act of 1973, Section 504) to ensure accessible transportation, considerations of passenger accessibility appear when vehicle components are discussed. There are various kinds of functional disabilities a person can have resulting from age, disease, or injury. The functional disabilities which impact on vehicle design are those which affect an individual's ability to enter and leave a vehicle, to move within the vehicle, and to be comfortable while the vehicle is in motion.

However, despite the fact that accessibility and other transit system requirements are important, a buyer does not have complete control over vehicle design. A buyer must investigate which aspects of a vehicle are standard and which are optional. This can be done by talking with vehicle manufacturers and suppliers.
To simplify the discussion of the large number of small transit vehicles available, the vehicles are grouped into a few categories. This grouping is based upon the construction method, the source of the vehicle (i.e., how and where the vehicle is assembled), and the seating capacity. Although seating capacity follows a general pattern (i.e., small buses seat more than body on chassis, which seat more than modified vans, which seat more than standard vans), there is some overlap among the categories. Figure 4 contains typical dimensions of the vehicle types.

*Higher value generally indicates the addition of air conditioning mounted on the roof.

Source for Vans, Modified Vans, and Body on Chassis: Reference 102.

**STANDARD VAN.** Standard vans have a typical seating capacity of from 5 to 15 passengers. Standard vans are available from automobile manufacturers and are part of their standard production line.

Vans offer several advantages. They are readily available for buying or leasing. Maintenance service and parts are not difficult to obtain. The initial capital cost is lower than that of other small transit vehicles, and they also offer greater maneuverability than do the larger vehicles.

The disadvantage of the van is that, because it is not designed for use in transit service, it is not durable as a transit vehicle. The expected life of a van in transit
service is three years, depending on a number of factors (such as the number of miles driven annually). In addition, entry into a van is difficult for some passengers because of the high first step and the low roof. The low roof also inhibits movement within the van, particularly to and from seats in the rear of the vehicle. If a lift or ramp is stored in the vehicle, it often protrudes into the van, further limiting seating space and maneuvering room. In order to clear the roof upon entry and exit, both the wheelchair occupant using the lift and the attendant must bend over.

MODIFIED VAN. The seating capacity of modified vans is approximately 9 to 16 passengers. A modified van is a standard van which has undergone some structural changes, usually made to increase its size and particularly its height. This is often accomplished by raising the roof (adding a bubble top). Other body changes include a widened door, and reinforced and insulated walls and roof. Chassis modifications can include an extended or widened wheelbase, heavy-duty brakes, and an improved suspension. Modifications to increase the safety and comfort of passengers include handholds for support, protective padding on hard surfaces, lower-rise steps at the entrance, roof ventilation for warm weather climates, and well-lighted interiors (102).

Modifications are not usually made by the original manufacturer. A modifier acquires the van and modifies it according to his agreement with the buyer. A modified van offers greater accessibility, less restricted interior movement, and more comfort than does a standard van.

However, care must be taken when raising the roof so that the structural integrity of the van is maintained (102). Some system operators claim that a raised roof makes the vehicle less stable (especially on open, windy roads), and that leaks often develop at the attachment line. Others say that the modifications add weight to the vehicle and reduce fuel mileage.

BODY ON CHASSIS. A body on chassis seats from 12 to 28 passengers and is typically composed of a light truck chassis underneath a special body. A supplier of a body on chassis will purchase a chassis produced by a company such as Chevrolet, Dodge, Ford, GMC, or International Harvester, and then manufacture the body. The body part is typically constructed around a steel frame and then attached to the chassis (Figure 5). This construction is similar to that of school buses.

Body-on-chassis vehicles offer certain advantages over vans. For example, they tend to be more durable than vans, having an expected life of five years, depending on a number of factors. Another advantage is that some body on chassis have dual rear wheels, making them more stable than vans and safer in accidents. They also offer more interior space, which is often necessary for stored
Figure 5. Typical Construction of a Body on Chassis

1. Chassis is purchased by the body builder.

2. A framework is built for the body.

3. The body is finished and the vehicle is complete.
A Typical Small Bus

Courtesy of Hausman Bus Sales

lift equipment and for wheelchair stations. Some body on chassis have transit-type folding doors and low steps for ease of entry. Another advantage is the larger fuel tank capacities of body on chassis, which can be especially helpful when fueling stops are infrequent.

However, body on chassis are not built on a durable transit chassis. Some operators comment that body on chassis have stiff suspensions which produce a bumpy ride. The process of adding a body to a chassis results in special problems, such as the body being insecurely attached to the chassis, inaccessibility of chassis components for repair and inspection, damage of electrical components during body assembly, etc.

**SMALL BUS.** A small bus seats from 23 to 35 passengers and has both a body and a chassis which are designed specifically for transit service. One supplier manufacturers the whole bus. Many of the components of a small bus are the same as those in standard transit vehicles (e.g., the engine, transmission, and axles). All of the small buses surveyed have diesel engines.

One of the major advantages of the small bus is its durability; for example, one of the small buses surveyed is expected to last from 10 to 15 years (120). The small bus offers the greatest amount of interior vehicle space, but is less maneuverable than the smaller vehicles. It also has a much higher purchase price. Another disadvantage is that the small buses which exist now have not been in operation for more than a few years; thus, little data is available on their performance.

**OTHER VEHICLES.** It should be pointed out that there are other vehicles which are currently in service and available for purchase, and others yet which are still under development. These are discussed only briefly in this report, because adequate information is available elsewhere.

1. **Standard School Buses (24)**

Standard school buses, which seat from 22 to 24 passengers, are a viable option; large fleets of these vehicles exist in many communities, including rural communities. This indicates that maintenance is available. By using an existing fleet, large financial investments for vehicles can be avoided while local interest in transit is tested (46). Leasing school buses is generally the cheapest method of obtaining vehicles.

However, there are disadvantages. Adults, especially elderly and handicapped people (who would probably be the prime users of such vehicles), are not comfortable in school buses, which are designed for children from 4 to 16 years of age. This is because of the high entrance steps, the relatively little space between the seats and the aisle, and the stiffness of the seats and suspension, all of which make for an uncomfortable and bumpy ride. Also, since school buses are not
Two Types of Paratransit Vehicle

designed for regular transit use, such use may decrease the life of the buses. School buses have large turning radii and are not as maneuverable as smaller vehicles. If a system wants to use only vehicles currently belonging to a school fleet, the number of vehicles available during peak travel times is limited. It is also important to note that there are regulations at all levels of government regarding the use of school buses for passengers other than pupils.

2. Station Wagons

Station wagons seat from 4 to 10 passengers. They can be readily bought or leased, and parts and service are also readily available. The capital investment is lower than that for the larger passenger-carrying vehicles, and resale is relatively easy (a factor not to be overlooked, as project needs may change over time) (46). Case studies have found that automobiles and station wagons are used principally in those rural areas in which volunteer drivers are part of a project, or as backup vehicles for systems in which van-size vehicles are not in regular service (46). Station wagons provide a smooth ride and are highly maneuverable. They are not, however, durable in transit service, nor do they allow passengers much movement within the vehicle.

3. Electric Vehicles (31,32,50,57)

Electric vehicles (EV's) have conventional chassis in which internal combustion engines have been replaced with electric motors and propulsion systems powered by acid lead batteries. EV's at their present state of development are considered by many to be mere novelties. In addition, there are few manufacturers producing such vehicles with a capacity of over four passengers. The primary attraction of electric vehicles is that they neither use petroleum fuels nor emit pollutants. They are also very quiet.

One of their disadvantages is that they cannot travel far without battery recharges. Research is being done, however, to combat this problem. High speed travel drains batteries faster and further reduces the time between recharges. Other disadvantages are related to the relatively recent use of EV's. For example, there are few service and repair facilities, and both drivers and mechanics need special training.

4. Paratransit Vehicle Prototype

The Office of Bus and Paratransit Technology within UMTA has established a program to design small, accessible transit vehicles. These vehicles, which carry a driver and up to six passengers, are intended for those services which do not require the seating capacity of vans or the larger vehicles. The prototype program may include an in-service demonstration of a number of vehicles.
DIMENSIONS.

1. Wheelbase and Exterior Length

The longer the wheelbase, the larger the turning radius. If the body of the vehicle is much longer than the wheelbase (has, in other words, a large overhang), the vehicle is less maneuverable and less stable.

2. Exterior Width

Some states regulate the width of buses. As shown in Figure 6, most states limit the width of buses to 102 inches. This regulation poses no problem for small transit vehicles since the widest small vehicles, the small buses, are only 96 inches wide.

3. Interior Height and Aisle Width

A 1977 survey of state governments who bought vehicles under the Federal Section 16(b)(2) program (Federal programs are discussed in Chapter IV), reported that height of from 72 to 74 inches is preferred, but that interior heights of over 65 inches make the vehicle more difficult to handle in headwinds. This handling problem most often occurs with modified vans which have altered centers of gravity due to roof modifications. Although headroom is increased in modified vans by raising the roof, it is also increased by lowering the floor. The increased headroom may or may not be necessary over both the aisle and seats, depending on the ability of passengers to slide into seats.

The aisle width should accommodate passengers and the assisting devices passengers may use, such as crutches, walkers, or wheelchairs. (See Figure 7 for general guidelines.) Wheelchairs may pose problems if wheelchair passengers must turn around within the vehicle. The seating arrangement can often be arranged to allow for this.

If passengers are expected to stand while in transit, as in fixed-route service, this should be taken into consideration when determining aisle width (84).

4. Door Height and Width

A door high enough to allow passengers to walk upright into the vehicle greatly increases accessibility, and can thus decrease the time it takes passengers to enter and leave a vehicle (thus reducing time requirements at stops). On standard vans the door height does not allow this, but on modified vans the door height is increased by either raising the roof or lowering the floor. The body design of the larger vehicles often takes this need into account. Passengers who find it difficult to stoop, or who use assisting devices, find they especially need a large door space.

A door which accommodates a wheelchair lift or ramp can be a problem on a standard van. To clear the top of the doorway, either the wheelchair passenger must bend his head or the attendant must stoop down and tip the wheelchair before wheeling it in.

**STEPS.** Entrance steps prevent 29 percent of the handicapped population from using a transportation vehicle (1). Some of these people can be helped by having a lower first step. A first step of from 7 to 13 inches from the ground is recommended by many sources. One report, summarizing various studies on step design, sees no advantage in having a step lower than seven inches; indeed, a step as low as four inches may cause passengers to trip (84). However, inclined handrails in the stairwell can assist passengers to negotiate steps. Retractable steps and stools are also used to provide a lower step. When stoops are used in this
way, however, additional time is required for the driver to place and store the stool. In addition, stools are not always stable.

One disadvantage of lowered steps is that they are susceptible to damage from raised objects on the road or from the vehicle stopping too close to a curb (46). Also, steps which can be totally enclosed by the entrance door are protected from ice, srow, mud, and rain, and are thus safer to use.

**SEATS.** The kind of seats and their layout will depend on the length of the trip and the smoothness of the ride.

Seats vary in their dimensions, construction material, and the method of attachment to the vehicle.
The seat dimensions should take into consideration the difficulty some individuals have getting into and out of the seat. For example, seats should have a restricted incline (84).

Padding may be desirable for long trips or for passengers who need the extra comfort.

The method of attachment chosen should take into account various considerations, such as the need to remove seats temporarily, and the ease of cleaning (84).

The seating layout is determined by the seating capacity and the positioning of the seats. Some typical seating arrangements are shown in Figures 8 and 9.

Suppliers may specify the seating capacity of the vehicle, but some operators have found the stated capacity to be overestimated for the level of comfort they desire.

There are several ways to position seats; forward, sideways, and diagonally. In general, side-facing seats are more accessible from the aisle. However, the motion of the vehicle can cause passengers to sway and even fall out of the seat during a sudden stop. A vehicle with a standard transmission may jerk during the shifting of gears and can be particularly uncomfortable for side-seated passengers on hilly terrain (25). Putting armrests on side seats can provide some support. An alternative to forward- or side-facing seats is seats at a 45 degree angle to the front of the vehicle. This arrangement increases seating room and leg room, but decreases the number of seats.

The placement of wheelchairs in a vehicle requires some adjustments. Seats can be installed so that their removal is possible to allow for securement of wheelchairs. In general, one wheelchair station is equal to two standard seats. Some vehicles have seats bolted into a track on the floor and some operators find this a convenient way to rearrange and remove seats. Some seats can be folded up so that wheelchairs can back up against them.

The positioning of a wheelchair passenger is important for safety and comfort since handicapped passengers cannot always control body movements. A secured wheelchair facing the rear of the vehicle with a padded support behind the chair and the occupant’s head is the safest position (40), but it does not allow for flexible seating arrangements, it requires more space, and it prevents passengers from seeing where they are going. (See the discussion on wheelchair securements below.)

Due to the limited interior space of vans and some body on chassis, transporting more than one wheelchair passenger at a time may require that the first wheelchair to enter the vehicle be the last to leave.

SUPPORT RAILS. These include stanchions (upright posts), overhead rails, and seatback rails. Overhead rails may be difficult for some to reach, and provide little stability during motion (84). Experience indicates that the optimal rail is from waist to shoulder height, but this is not feasible, however, with high density seating. A viable setup is one using a hand-over-hand reach by alternating stanchions and seatback rails (84).

FLOOR COVERING AND SEAT MATERIALS (85). Vehicle floors are covered not just for looks, but for many functional reasons as well. Carpeting, for instance, absorbs interior noise and provides a soft surface to walk on.

A skid-resistant rubber mat cemented to the floor is an alternative to carpeting. It is less troublesome to maintain, and is recommended over carpeting when some type of textured or webbed material is specified to allow adequate protection in directions both parallel to and perpendicular to a passenger’s line of motion.

DOORS. There are three major types of doors: bifold doors, sliding doors, and conventional, automobile swing-out doors. Large vehicles generally use bifold doors. Most vans are built with sliding doors; operators have complained that these doors are not durable in a transit service where the doors are constantly being opened and shut (49). Swing-out doors are easier to open than sliding doors; they’re also lighter and less expensive (93). Some operators have indicated that swing-out doors on the wheelchair entry are not provided with adequate latches to keep the doors open while the lift is in operation. Unlike other types of doors, swing-out doors require extra clearance for opening.

In general, depending on the placement of the farebox, the door which accommodates a wheelchair lift or ramp is best placed to the rear of the front wheels. This allows direct access to the passenger area and gives the wheelchair user more space in which to maneuver upon entering the vehicle.

Emergency exit doors are generally in the rear of a vehicle. This may prevent the placement of a seat along the rear of the vehicle.

The placement of locks and warning buzzers on all doors and safety bumper cushions over each doorway is recommended (49).

CHASSIS. Some of the chassis components for vans and body on chassis are shown in Figure 10.

1. Engine
The gasoline and the diesel engines are the two major types of engines in transit vehicles. Within these types there are different sizes and configurations. The
Figure 10. Basic Components of a Van Chassis
exact engine chosen depends on the weight of the vehicle and on the nature of the
service for which it will be used. Manufacturers and experienced operators can
provide advice in this matter.

Most buses are diesel. The major difference between gas and diesel engines
is that gas engines ignite electrically, whereas diesel engines ignite by friction and
compression. Diesels do not have the electrical components (such as points,
plugs, wires, and condensers) that gasoline engines require, since diesels do not
need carburation (the mixing of air and fuel).

The advantages of diesels are:

- Cheaper fuel
- Better fuel mileage — a savings in fuel used of from 20 to 40 percent
- Longer engine life, longer warranties; engine failure is often the major cause
  of vehicle retirement
- Better reliability and fewer maintenance costs.

The disadvantages of diesels are:

- Higher initial costs
- Difficulty starting in cold weather
- Higher noise levels
- The need for different tools and for mechanics familiar with diesels.

These disadvantages can often be ameliorated. The purchase price may be
offset by the lowered operating cost. Heated, indoor storage or special equipment
can help the engine start in cold weather. Engine compartments can be insulated to
keep noise from the passenger compartment. For example, the integrated dial-a­
ride and fixed-route system which operated in Ann Arbor, Michigan insulated the
engine with a 1-inch thick fiberglass material to minimize the escape not only of
noise, but also of heat and fumes.

Since fuel costs continue to rise, another important aspect of engine selection
is its effect on fuel efficiency. (Fuel efficiency is also affected by such factors as trip
length, weather, condition of vehicle, road conditions, speed, driving habits of
operator, weight of the vehicle, and vehicle accessories.)

2. Transmission

It is important to have the proper transmission for the engine model and the
proper gear ratio for the speed at which the vehicle will commonly be traveling. This
provides a safer trip and keeps the wear on the drive train low.

A survey of modified vans and body on chassis used in specialized trans­
portation found that transmissions last between 60,000 and 80,000 miles before
requiring replacement.
3. Suspension

As with all the components, heavy-duty shock absorbers and the heaviest possible suspension are needed to carry the heavy bodies on the chassis and to withstand the rigors of transit service. The heavy bodies can cause front ends and tires to wear quickly. A stiff suspension can produce an uncomfortable and bumpy ride. A smooth ride is facilitated by heavy-duty shock absorbers, and by high-capacity springs and axles. A high-capacity suspension is especially necessary with poorly paved roads and constant stop-and-start driving.

4. Brakes

One of the first vehicle difficulties an operator cites with vans and body on chassis is brake failure. Even with heavy-duty brakes, brake pads and shoes wear quickly and have to be replaced. For this reason, front-wheel disc brakes and rear-wheel drum brakes are recommended (49, 102). This lengthens the brake life and improves the stopping performance. Rear disc brakes are not considered a necessity, since front brakes absorb most of the force in stopping (102).

5. Electrical System

Optional equipment such as air conditioners, extra lighting, radio communication, ancillary heaters, and wheelchair lifts place greater demands on the electrical system. For this reason, heavy-duty alternators, of from 90 to 120 amps, are recommended for vehicles other than small buses (102). Small buses use alternators ranging from 140 to 190 amps.

Heavy-duty batteries are also advised for all vehicles. Operators have had trouble with the ability of heating and cooling units to keep a consistent temperature throughout the vehicle.

A few comments concerning electrical wiring are in order. In some cases, in the process of modifying vans or placing bodies on chassis, electrical wires have been interfered with, resulting in electrical difficulties. Uniformity in the routing and color coding of cables facilitates maintenance. Lastly, precautions can be taken to protect electrical cables from mud, snow, and ice.

AIDS FOR THE VISUALLY OR HEARING IMPAIRED.

1. Colors

Colors chosen for the vehicle exterior may reflect personal taste, but it should be kept in mind that distinctive colors make a vehicle more visible to visually-impaired passengers. Furthermore, when colors in the interior are utilized to create a contrast between the seats and the floor (for example, dark seats and a light floor), visually-impaired passengers are able to move more easily within the vehicle (44). Some systems paint the steps or step edges yellow or orange in order to make them easier to see (60, 78).
2. Lighting
Lighting in the vehicle and stairwells facilitates movement (44, 46).

3. Informational Devices
Special chimes or PA systems can announce a vehicle's arrival to visually-impaired persons. Allowing a person to sit close to the driver permits the driver to communicate more easily with the passenger (44).

AIDS FOR THE NONAMBULATORY OR SEMI-AMBULATORY.

1. Boarding Devices
There are two basic devices to help passengers who can not use steps. Although a discussion of both of these follows, it should also be noted that emergency evacuation of the vehicle should also be taken into account when choosing a boarding device. Appendix B contains a list of lift and ramp manufacturers.

a) Lifts
There are two major types of lifts: electromechanical lifts, which use belts, chains, or cables to operate; and electrohydraulic lifts, which use cylinders of fluid (fluid pressure) to operate.

A lift permits access for a wheelchair user by first lowering a platform to ground level, allowing the user to wheel onto the platform, and then raising the platform to the same level as the vehicle floor so that the user can wheel into the vehicle. Some systems permit semi-ambulatory passengers to use a lift while they are standing. Vans, modified vans, and body on chassis generally store lifts vertically, inside or outside the vehicle alongside a door. However, lifts can also be stored on top of the vehicle. Small buses usually have lifts which serve as steps for ambulatory passengers and which unfold from the step configuration into a platform. These lifts are called active lifts or step lifts. (References 14, 15, 97, 99 contain discussions of active lifts in service.) Figure 11 lists safety guidelines recommended by many sources for use in lift purchase specifications or installation.

The location of the lift is important (102). Storing a lift on the outside of a vehicle affords more seating and maneuvering room inside the vehicle. Lifts stored outside the vehicle are usually attached to the rear door, because placement above the bumper is convenient, and because it is dangerous to have an unusual protrusion on the side of the vehicle. However, exposing the lift to wet weather or snow may necessitate that the lift be cleaned before each use, and may also increase the possibility that the lifting mechanism will freeze. In addition, a lift located outside of the vehicle is more easily damaged in a collision.
Protective Padding on a Lift Stored Inside a Vehicle

Figure 11. Recommended Safety Features for Use of Wheelchair Lifts

- Padding of hazardous protrusions and exposed edges of lift when stowed in vehicle.
- Pad upper frame of lift doorway.
- Enclosure of exposed parts and moving parts.
- Interlock system on vehicle brake or transmission to prevent vehicle movement while lift is in operation.
- Shut-off mechanism, which stops lift operation, activated when lift strikes an obstruction.
- In case of a power failure, use manual override to allow lift operation.
- Mechanism to ensure slow free fall of lift platform in the event of a power failure.
- Minimal vibration to permit users to stand and retain their balance; and to avoid the loosening of fasteners for joining parts.
- Back and side plates on platform to keep wheelchair from rolling off.
- Slip resistant material on platform.
- Audio and visual signals to alert people when lift is in operation.

Source: References 15, 74, 85, 95, 97, 102, 118.

Rear-door lifts are preferred in areas where there are streets which are one way, or streets which have roadside ditches, tall grass, heavy snow, and/or narrow driveways.

Side-door-mounted lifts are more common in urban areas where curbside pickups are frequent. If a vehicle stops in the street rather than in a driveway, it is less dangerous for passengers to board from the sidewalk than from the street behind the vehicle. The risk of a passenger being struck by another vehicle is greater on the street.

The cost of acquiring and utilizing a lift is expensive. Figure 12 lists the price range of lifts. Vehicle operating costs are affected by lifts in a number of ways. Fuel costs may increase due to the added weight of the lift. Increased driver training and higher driver wages due to a driver's increased duties and responsibilities for passenger assistance may be necessary. In addition, maintenance costs may
increase, because of the need for additional training for mechanics, for a parts inventory, and possibly for special tools. Another impact that a lift may have on a service is that a revenue-producing service may find that the reduced seating and the increased time spent at some stops affects revenues.

b) Ramps

There are fewer commercially available ramps than there are lifts. Ramps are often designed and made by individual vehicle suppliers to fit into their own vehicles. Ramps cost less than lifts, are installed more easily, operate more simply, and require less maintenance. They are attached on top of or underneath the vehicle floor. They are stored in a folded vertical position inside the vehicle or horizontally underneath the floor.

Generally, ramps are operated manually. Although a ramp which rests on a curb rather than on the street can reduce the steepness of the incline, most wheelchair passengers must be assisted up and down the ramp, even if the ramp rests on the curb rather than on the street (and is therefore less steep). This requires some strength on the part of the assistant or driver and has caused back injuries in some cases (88, 95).

Passengers using walkers, canes, or crutches have difficulty walking on an incline (85). It is recommended that a boarding chair (a folding wheelchair) be used to help these passengers board.

Although both lift platforms and ramps can become slippery in wet weather, it is more of a problem with a ramp since the assistant may also slip.

2. Wheelchair Securements

Wheelchair securements, also called restraints or tiedowns, are devices located inside the vehicle and attached to the vehicle in order to hold a wheelchair and its occupant in place while the vehicle is moving, or during a sudden stop or

*Higher price includes installation costs.*
Two Types of Wheelchair Securements

This is done in order to protect both the wheelchair occupant and the other passengers. Devices currently used include belts, chains, metal brackets, and bars. Appendix B contains a list of securement manufacturers.

Most securements are operated manually. They are attached to the wall or floor of the vehicle or to the bottom of a foldable seat, and fasten onto the wheel or frame of the wheelchair. The design and location of the securement, and the disabilities and dexterity of the wheelchair user, affect the amount of driver assistance necessary to apply a securement device (96).

One problem operators have identified is that not all restraints can be secured to all wheelchairs. Often this is due to differences in the width of the tires or in the type of wheel. A recent study recommended that wheelchairs have a standard fixture which attaches to a standard securement (96).

Another concern of system operators and users is the need for valid testing of securements to ensure their reliability in a sudden stop. Some testing has been undertaken, but the results have shown that some restraints and some wheelchairs do not hold up in simulated crashes (90, 91, 96).

The need for backup vehicles

The number of vehicles an operator chooses to buy is integrally related to the service level to be provided, the size of vehicle chosen, and the operator's financial capabilities.

However, another important consideration in selecting the number of vehicles to acquire is the need for backup vehicles to be used in case vehicles are out of service due to breakdowns or routine servicing. Although very small systems may not be able to afford extra vehicles, situations in which vehicles are constantly out of service can severely affect the system's operation (12, 55).

The number of backup vehicles necessary is dependent upon the:

- Maintenance system’s capability to acquire parts and perform maintenance on the base fleet quickly
- Possibility of routine care being done during non-operating hours (e.g., nights and weekends)
- Ability to limit breakdowns by routine preventive maintenance
- Feasibility of storage

Some sources suggest formulas to calculate the number:

- For a fleet of less than 7 buses, have 1 spare; for a fleet of between 8 and 20...
buses, have from 2 to 3 spares; for a fleet of greater than 20 buses, have 1 spare for each 10 vehicles (46).

- 10 percent of a regular fleet should be spare (13).
- From 25 to 30 percent of a small fleet should be spare (55).

In some cases, spares are vehicles which are at the end of their life, but which have undergone some repair (e.g., new engines) to permit their functioning on a part-time basis. However, some operators have found that frequent breakdowns of the regular fleet have required that spare vehicles operate full time.

**uniformity of the fleet**

Inexperience has demonstrated the importance of the uniformity of vehicles within a system fleet. Of course, not all systems have control over which vehicles they operate. Many new systems start a service with a variety of vehicles donated, leased, or bought from other agencies. Systems which are required by law to purchase a vehicle having the lowest bid may have to buy different vehicles each time a bid is awarded. In addition, the selection of vehicles offered on the market changes rapidly.

Nonetheless, a uniform fleet offers certain advantages. The primary advantage in uniformity is the ease of maintenance and repair. Mechanics need only be familiar with one type of vehicle, and it is simpler and cheaper to acquire and keep a parts inventory. It may also increase the efficiency of the maintenance operation, since as problems develop in one vehicle, steps can be taken to see that the problem does not recur with the other vehicles. The Integrated Transit Demonstration Project in Rochester, New York, used different types at one time in order to determine the best vehicle for future selection (55). As a result of a high number of vehicle breakdowns, the analysis of this experiment recommended that a system choose only one type of vehicle with a proven reliability record (77). In addition to maintenance, a fleet uniform in passenger capacity and seating arrangement makes scheduling and dispatching simpler because vehicles are interchangeable.

The main disadvantage of a uniform fleet is that its very uniformity limits its responsiveness to the varying demands placed upon it (35). An evaluation of the Section 147 Rural Public Transportation Demonstration Program revealed that there was a greater than anticipated need for one or two large vehicles for those systems which had a number of vans or small buses (12).
III PROCUREMENT

VEHICLES CAN BE procured in three ways: acquired from an existing fleet, leased, or purchased. Most of this discussion is concerned with purchasing since it can be the most complicated and time-consuming procurement process.

The last part of this chapter looks at funding sources, primarily governmental sources. Appendix C has a chart which lists and briefly describes many Federal programs.

---

**acquisition from an existing stock**

It is not always necessary to purchase a new vehicle. Vehicles can sometimes be acquired for use from an existing stock of vehicles, such as a school bus fleet, another transit service, or a social service agency. Many systems which intend to provide service for a number of organizations have the vehicles donated to them by the organizations for which they are providing service (51). These vehicles may also be leased by the agencies to the service provider, sometimes for a token fee of one dollar.

---

**leasing**

Leasing a vehicle is considered an option when:

1. **Funds are limited in starting a new system, or when the system may not be implemented on a permanent basis.**

   Although leasing increases the operating costs of a project, capital costs are deferred (13). If funds do become available, or the system becomes permanent, the option of buying the vehicle at the end of the lease agreement may be considered.
2. **Start-up time is limited.**

The application time for governmental funding can be lengthy. In addition, local, state, and Federal laws may require a system operator using public funds to acquire vehicles through a formal bid process, which may be time consuming.

In those cases, systems lease vehicles, because vehicles can be leased more quickly than they can be bought. Some systems simply lease vehicles while they’re waiting to receive grant money.

3. **The long-term service needs of a system are unknown.**

Leasing allows a system to be flexible and to adapt to changes in vehicle needs.

4. **Minimal administrative and accounting work is required.**

A leasing agreement may be a full-service contract, with maintenance, insurance, and licensing provided by the lessor. The system provider thus avoids the administrative costs and time needed to provide and arrange for these services. Accounting and record keeping is simplified, because only lump-sum payments are necessary.

5. **Leasing is cheaper than purchasing.**

Leasing agreements are usually based on a set amount of mileage beyond which the lessee is charged for each additional mile traveled. (The example in Figure 13 demonstrates one process of cost comparison.) It is important to note that a short-term lease may be more expensive on a yearly basis than a long-term lease. For example, a 1-year lease may contain a charge for the majority of the depreciation of the vehicle, a longer lease would have the depreciation spread out over several years.

---

A major advantage of purchasing is the greater variety of vehicles from which to choose. Vans and school buses are generally available through lessors, but other vehicles frequently are not, as they are usually built to order for a limited market. Most sources agree that the long-run costs of purchasing a vehicle are less than the costs of leasing. Purchasing also permits a system to build up equity.

If an operator relies on governmental funding assistance, a time-consuming application and approval process may have to be followed in order to purchase vehicles. Therefore, a considerable amount of time may pass before an operator can ask vehicle suppliers to offer prices for their vehicles (to begin the bid process). For example, the DOT funding programs require the applicant to follow a specified
In the sample case below, an operator wishes to acquire seven vehicles. Given specific conditions, calculations are made to determine whether leasing or purchasing vehicles is less costly. The calculations for the purchase option are somewhat complicated, so it may be desirable to have someone knowledgeable in accounting principles to assist individual operators in comparing costs.

### Leasing

**Conditions:**
- 7 vehicles
- $6,000 yearly cost per vehicle

**Equation:**

\[ 7 \text{ vehicles} \times \$6,000 = \$42,000 \text{ per year} \]

### Purchasing

**Conditions:**
- 7 vehicles
- $35,000 per vehicle
- 10-year life
- $1,000 salvage value
- 10% finance charge

**Equation: (without grant)**

\[ [ \text{cost per year without grant} ] = \frac{[ \text{purchase price} ] \times [7 \text{ vehicles}] \times [\text{capital recovery factor} \times (10\% \text{ for 10 years})]}{\text{minus}} \]
\[ [\text{salvage value}] \times [7 \text{ vehicles}] \times [\text{sinking fund factor} \times (10\% \text{ for 10 years})] \]

equals yearly cost.

The equation for our sample:

\[ \$35,000 \times 7 \times 0.16275 - \$1,000 \times 7 \times 0.6275 = \$39,434.50 \text{ per year} \]

**Equation: (with 80% capital grant)**

\[ \text{per vehicle} \times \text{7 vehicles} \times \text{cost per year without grant} \times 0.80 \]

\[ \text{equals yearly cost.} \]

**Thus, for our sample:**

\[ \$39,434.50 \times 0.2 = \$7,353.50 \text{ per year}. \]

Source: Reference 9.
planning process. Applicants must have their capital request included in an area-wide plan approved by local and state agencies. Figures 14 and 15 show the typical procurement process for UMTA's Section 3, Section 5, and Section 16(b)(2) programs and for the Federal Highway Administration's (FHWA's) Section 18 program. Delays can occur at each step. For example, Section 3, Section 5, and Section 18 require that the grant recipients reach signed agreements with labor organizations before equipment is purchased. This sometimes causes extensive delays.

Some states which procure vehicles for grant recipients have had to delay the bid process until the local applicants send the state their local matching share of the Federal subsidy. The California Department of Transportation (Caltrans) has set up a revolving fund, with enabling state legislation, in order to have money available while recipients are in the process of collecting their matching share to send to the state. Each repayment to the fund is used as a future float until the next round of grant recipients send in their local share. This has enabled the state to complete the procurement process in from 6 to 8 months less time than the original 15 to 34 months it had been taking (17).

It is important to procure the vehicles as quickly as possible. If there is a significant delay, the local commitment to match state or Federal subsidies may wane, the prices of vehicles may increase, or the needs of the transportation service may change, requiring a different vehicle than was originally ordered.

**BID PROCESS.** Requesting bids is the most common procedure for procuring a vehicle, one reason being that it is required by public funding sources. A bid is basically a statement of which vehicle, and with what features, a supplier will sell to a buyer at which price. If the vehicle the buyer wants is specified to bidders, a comparison of bids allows the buyer the opportunity to purchase the best buy.

Generally, governmental funding sources require a formal advertisement for bids and a fair and open competitive process of receiving and analyzing bids. There are three common methods of advertising for bids: invitations can be mailed directly to suppliers, they may be printed in newspapers, or they may be printed in trade journals. (See Figure 16.) In addition, government regulations may require specific clauses and provisions in the advertisement, and in the contract documents between the buyer and seller.

The Federal government outlines its regulations concerning the procurement and selection of equipment, subsidized in whole or in part by Federal funds, in the following Office of Management and Budget Circulars:

  In which local vehicle request is included
  3 mos.

- UMTA Regional Office authorization for State DOT to proceed
  3 mos.

- Copies of application to appropriate offices
  1 mos.

- Department of Labor (DOL) review
  for 13(c) compliance
  3 mos.

- DOL certification of 13(c) compliance
  3 mos.

- Local bid received
  1-2 mos.

- Local bid award
  1 mos.

- State颁 award
  1 mos.

- Local vehicle delivery
  3-12 mos.

**This represents the approximate (minimum and maximum when two numbers are given) time frame in months for completing a step.

For Sec. 3 and 5 the time frame from preliminary application to vehicle delivery is 11-29 months. For Sec. 16(b)(2) the time frame from preliminary application to vehicle delivery is 14-26 months. The maximum times will be required as vehicles requested are customized to meet special needs.

* FHWA = Federal Highway Administration
**Figure 15. Vehicle Procurement Flow Chart (Nonurbanized Area Grant Programs)**

1. **Vehicle need must be identified in the following planning document:**
   - Short Range Development Program
   - This vehicle must be approved by the regional planning or transportation agency.
   - All planning documents are forwarded to FHWA Division Office and UMTA Regional Office for approval.

2. **Local agency files Sec. 18 preliminary application including evidence of local match**

3. **State Department of Transportation (DOT): Review**
   - Steps:
     1. Review for funding & project compliance
     2. Include in program of projects (if for UMTA funding)
     3. Notify State of Sec. 18 program (in which local vehicle request is included)
     4. Send letter of labor certification to the Department of Labor (DOL)

4. **Final Division Office forwards the program of projects (if for UMTA funding)**

5. **FHWA Division Office review and authorization to State DOT**

6. **State DOT authorization to local applicant**

7. **Local bid process**

8. **State bid award**

9. **Local vehicle delivery**

10. **State DOT notification to local applicant of award and proposed delivery date**
    - Steps:
      1. Ask applicant to have no own match ready
      2. Enter into a service contract with applicant

11. **Local agency files Sec. 16(b) preliminary application including evidence of local match**

12. **State Department of Transportation (DOT): Review**
    - Steps:
      1. Review for funding & project compliance
      2. Include in program of projects (if for UMTA funding)
      3. Notify UMTA of Sec. 16(b) program (in which local vehicle request is included)

13. **FHWA Division Office forwards the program of projects (if for UMTA funding)**

14. **State DOT authorization to local applicant**

15. **Final Division Office review and authorization to State DOT**

16. **State DOT authorization to local applicant**

17. **Local bid process**

18. **State bid award**

19. **Local vehicle delivery**

20. **State DOT notification to local applicant of award and proposed delivery date**
    - Steps:
      1. Ask applicant to have no own match ready
      2. Enter into a service contract with applicant

FHWA = Federal Highway Administration

*This represents the approximate (minimum and maximum when two numbers are given) time frame in months for completing a step.

For Sec. 18 the time frame from preliminary application to vehicle delivery is 12-23 months. For Sec. 16(b) the time frame from preliminary application to vehicle delivery is 12-24 months. The maximum times will be required as vehicles requested are customized to meet special needs.*
STATE OF ILLINOIS
DEPARTMENT OF TRANSPORTATION
DIVISION OF
PUBLIC TRANSPORTATION
NOTICE TO BIDDERS

Separate sealed bids for:

1. Twenty-two (22) buses especially designed to transport elderly and handicapped persons and having a capacity for 12-16 passengers. (Bid Package A)

2. Up to thirteen (13) buses especially designed to transport elderly and handicapped persons and having a capacity for 18-24 passengers. (Bid Package B)

Bids will be received by the Illinois Department of Transportation at the offices of the Illinois Department of Transportation, Division of Public Transportation, 300 North State Street, Room 1002, Chicago, Illinois 60610, until 11:00 o'clock A.M. (CST), July 23, 1980, and at that time publicly opened and read.

BIDS WANTED

This request for bids is being undertaken on behalf of the purchasers, private non-profit agencies, in order to have applications for capital grant assistance that have been approved by the Federal Government under the provisions of Section 16(b)(2) of the Urban Mass Transportation Act of 1964, as amended.

Any and all contracts resulting from these bids are subject to the terms of the financial assistance contracts between the Illinois Department of Transportation and the United States Department of Transportation and between the purchasers and the Illinois Department of Transportation.

Any individual, firm, partnership or corporation appearing on the United States Comptroller General's list of ineligible contractors will not be an eligible bidder. All bids and related documents will be subject to financial assistance contracts between the District and the U.S. Department of Transportation, Urban Mass Transportation Administration (UMTA) and between the District and the U.S. Department of Transportation and its local operators. All bidders will be required to certify that they are not on the Comptroller General's list of ineligible contractors. The successful bidder will be required to comply with all applicable Equal Opportunity Laws and Regulations.

Bids must be accompanied by a certified or bank check or acceptable surety bond in an amount not less than five percent (5%) of the total bid price. The check or surety bond will be returned to unsuccessful bidders. Such bid bond received by a successful bidder will be returned to unsuccessful bidders. Such bid bond received by a successful bidder will be held until said successful bidder furnishes a performance bond with surety or certified or bank check for the full amount (100%) of the contract to the District. Upon receipt of said performance bond, the bid bond will be returned to the successful bidder.

A Bidder shall submit their bid in a sealed envelope and shall indicate on the face of their bid envelope the following: "Bid for Lift-Equipped Passenger Vehicles."

Bids will be received up to but not later than 11:00 a.m. local time, October 6, 1980. At that time, the bids will be publicly opened and read aloud at the District's office. Bids must remain in effect for thirty (30) days from the bid opening.

Requests for copies of the Technical Specifications, General Specifications, and Bid Forms and all inquiries related thereto shall be directed to the above address. Telephone inquiries may be made to either the above address or Mr. Samuel G. Brinings, Transit Planner, at (203) 247-5329.

All bids and related documents will be subject to financial assistance contracts between the District and the U.S. Department of Transportation, Urban Mass Transportation Administration (UMTA) and between the District and its local operators. All bidders will be required to certify that they are not on the Comptroller General's list of ineligible contractors. The successful bidder will be required to comply with all applicable Equal Opportunity Laws and Regulations.

Bids must be accompanied by a certified or bank check or acceptable surety bond in an amount not less than five percent (5%) of the total bid price. The check or surety bond will be returned to unsuccessful bidders. Such bid bond received by a successful bidder will be held until said successful bidder furnishes a performance bond with surety or certified or bank check for the full amount (100%) of the contract to the District. Upon receipt of said performance bond, the bid bond will be returned to the successful bidder.

The District reserves the right to accept any bid or reject any and all bids and to waive any irregularities.

Dated: August 12, 1980
By: ARTHUR L. HANDMAN
Executive Director

The Greater Hartford Transit District (the "District") hereby gives notice that it will receive sealed bids for the purchase of up to twenty-three (23) 12-passenger vehicles, seventeen (17) of which shall have wheelchair lifts.

Bids shall be submitted on forms furnished by the District and shall be addressed to:

Mr. Arthur L. Handman
Executive Director
Greater Hartford Transit District
179 Allyn Street
Hartford, CT 06103

Bidders shall submit their bids in a sealed envelope and shall indicate on the face of their bid envelopes the following: "Bid for Lift-Equipped Passenger Vehicles."

Bids will be received up to but not later than 11:00 a.m. local time, October 6, 1980. At that time, the bids will be publicly opened and read aloud at the District's office. Bids must remain in effect for thirty (30) days from the bid opening.

Requests for copies of the Technical Specifications, General Specifications, and Bid Forms and all inquiries related thereto shall be directed to the above address. Telephone inquiries may be made to either the above address or Mr. Samuel G. Brinings, Transit Planner, at (203) 247-5329.

All bids and related documents will be subject to financial assistance contracts between the District and the U.S. Department of Transportation, Urban Mass Transportation Administration (UMTA) and between the District and its local operators. All bidders will be required to certify that they are not on the Comptroller General's list of ineligible contractors. The successful bidder will be required to comply with all applicable Equal Opportunity Laws and Regulations.

Bids must be accompanied by a certified or bank check or acceptable surety bond in an amount not less than five percent (5%) of the total bid price. The check or surety bond will be returned to unsuccessful bidders. Such bid bond received by a successful bidder will be held until said successful bidder furnishes a performance bond with surety or certified or bank check for the full amount (100%) of the contract to the District. Upon receipt of said performance bond, the bid bond will be returned to the successful bidder.

The District reserves the right to accept any bid or reject any and all bids and to waive any irregularities.

No. A-104 — Comparative Cost Analysis for Decision to Lease or Purchase General Purpose Real Property

UMTA has more detailed regulations for its aid recipients contained in its External Operating Manual Section III-C. Figure 17 lists the types of required clauses and provisions. For all proposed and formally advertised contracts costing more than $2,500, the manual states that UMTA shall make a prebid analysis and review. The External Operating Manual does not, however, govern the 16(b) (2) program. Recipients of 16(b) (2) funds are expected to follow local bid regulations; UMTA does not review the proposed contracts. The FHWA Section 18 program currently expects that local bid requirements be followed by funding recipients of capital assistance.

Source: Reference 115.
Most bid procedures follow the general process outlined in Figure 18.

Figure 18. Typical Bid Process

- Contract documents are drawn up.
- Advertisements are posted and bids are received.
- Bids are opened at public meetings and read aloud.
- Bids are analyzed.
- One bidder is awarded the contract.
- Vehicles are delivered by contractor.

Allowances are usually made in the process for bidders to contest specifications, to ask for approval of what they consider an equivalent specification, or simply to clarify specifications. One method is to have a prebid conference, usually held shortly after bidders have picked up the buyer's proposed contract. This conference provides a forum for the buyer and for the potential bidders to clarify provisions. They may also discuss whether the provisions in the contract are reasonable (i.e., that most suppliers can meet those provisions and bid on the contracts). This encourages greater competition. As a result of this conference, addenda to the proposed contract may be issued.

Another way of eliciting feedback from suppliers is to ask them to submit written comments soon after the bid opens. The buyer's analysis and comments may result in amendments to the contract.

The time taken by the bid process varies depending upon the regulations a buyer is following and upon the time constraints a buyer has set. Figure 19 shows...
Figure 19. Sample Bid Process Timeline

- Advertisement for Bids Begin (Day 1)
- Amendments Submitted (Day 2)
- Buyer Responds (Day 35)
- Final Amendments Completed (Day 42)
- Bid Opens (Day 45)
- Bid Awarded (Day 75)
- Final Paperwork Completed (Day 85)
- First Vehicle Delivered (Day 175)

The delivery time, the time between the awarding of a contract and vehicle delivery, can be specified by the buyer in the proposed contract. Alternatively, a buyer may allow the bidders to set the time in their bid. One advantage of this is that the proposed delivery time, like the price, becomes an item for comparison in the bid analysis. It may also keep bid prices lower, because bidders may raise prices in an effort to meet a buyer’s early completion data.

Suppliers have indicated that delivery can take anywhere from 2 to 12 months, with delivery for small buses averaging around 12 months. This depends on the suppliers’ manufacturing capacity and on their ability to obtain the chassis (in the case of modified vans and body on chassis) and parts. Sometimes conditions beyond the suppliers’ control delay delivery; labor strikes, for example, can delay the suppliers’ receipt of parts. Although provisions can be included in a contract for a supplier to pay for damages resulting from a delay in delivery, many operators feel that the inconvenience to their service caused by a delay cannot be adequately rectified by liquidated damages.

**SIZE OF ORDER.** In general, the larger the purchase order, the lower the price of each vehicle. It may also be less expensive to get a vehicle with special specifications or options if a large number of these vehicles are ordered at one time.

In this regard, Caltrans has considered investigating the possibility of a small transit vehicle consortium among several states. It believes that joint purchasing should improve vehicle quality and lower the cost.

On the other hand, large orders may lengthen the delivery time for the full order. For example, when the Iowa Department of Transportation procured vehicles for their 16(b) (2) program applicants in years past, procurement time was from 15 to 18 months. During the first year in which applicants procured their own vehicles, delivery took only from three to six months.

**CONTRACT DOCUMENTS.** Contract documents are comprised of two major parts, the front-end documents and the technical specifications. Buyer inexperience in writing the contract, and especially the technical vehicle specifications, has resulted in delays. Some of these inexperienced buyers have speeded their procurement by using state and local highway or transportation departments to assist them. In many states, it is the state agencies or experienced transit authorities which actually handle the procurements.
1. Front-end Documents

The type of contract documents and phrases used vary. However, there are some basic components of the front-end documents.

- Instructions to bidders — details the bid process, including qualifications expected of bidders, bonding information, data to be submitted with bid, how a bidder can request clarification or addenda, etc.
- General provisions — details the role of buyer and supplier in the contract concerning items such as payment, delivery, inspection, termination of contract, warranty; also state and Federal provisions.
- Bond forms — Bonds provide collateral against a bidder’s failure to perform. There are three types in common use. A bid bond guarantees that the bidder will sign the contract if awarded the project. A performance bond guarantees that the supplier will complete the project. And a payment bond guarantees that the supplier will pay for all labor and material used in the project.
- Bidder’s proposal — lists what the bidder will provide, such as the quantity of items to be produced, prices, technical specifications, servicing and parts, etc.

There is one general provision which deserves a separate discussion, because it has been a problem in many cases. It has been reported that problems have arisen from the warranty agreements for modified vans and body on chassis (102). The chassis and bodies are generally manufactured by different companies and each manufacturer warrants his own product. A wheelchair lift may be warranted by the vehicle supplier; otherwise repairs under warranty are done by the original manufacturer. In areas where chassis or body dealers are not readily available, arrangements can be made for local mechanics to perform repair work and be reimbursed by the manufacturer under the terms of the warranty.

The real inconvenience to the buyer is not the need to deal with several dealers, but the disputes which arise when responsibility for a defect is unclear. The disputes can result in delays in repairs. A warranty agreement designating the supplier as responsible to the buyer for all warranty work has been used to alleviate this problem.

2. Technical Specifications

Technical specifications are the part of the contract which determines the actual components, construction, and performance requirements of the vehicles. Specifications can be phrases or drawings.
Specifications can vary in the items included and in the style of presentation. However, specifications do follow a general pattern. Appendix E contains a sample outline of a technical specifications document.

Specifications can dictate a design standard or a specific performance level. For example, the following two specifications concerning axle capacity show this difference.

- Design oriented*
  “Front axle capacity 4,000 lbs minimum
  Rear axle capacity 11,000 lbs minimum”

- Performance oriented**
  “The combined front and rear axle capacities, as rated by the axle manufacturers, must equal or exceed the total "net" curb weight of the coach, plus a full seated load, plus standing passenger load of 50 percent of seated passenger load, plus operator, at 150 pounds per person.”

Buyers have noted that it is desirable to allow the supplier flexibility in construction and not to eliminate bidders who can meet the desired performance level but not a strict standard. When specific figures are used in a specification they are often written as a minimum standard, or expressed as a range between a minimum and maximum. On the other hand, the specification should be tight enough to guarantee that the low bid a buyer accepts is for vehicles of the quality desired.

**BID ANALYSIS.** In general, bid analysis requirements set the low bid (lowest-priced vehicle) as the basis upon which a contract is awarded. UMTA requires that awards be made to the "lowest responsive and responsible bidder"; otherwise, UMTA approval is necessary (115).

One alternative is to use the life-cycle of the vehicle, rather than the initial cost, as the determining cost. Life-cycle costs include the acquisition costs, operating costs, and maintenance costs; in other words all the costs associated with a vehicle's useful life.

Appendix F contains one method useful for computing life-cycle costs. (See Figure 20.) However, it is difficult to document these costs, and disputes concerning figures may not be easy to resolve. In addition, operators have claimed that their budget constraints do not permit the acquisition of a vehicle which has a high initial cost even though it may be less expensive in the long run.

Figure 20. Computing Life-Cycle Costs

1. Collect Life-cycle cost data

2. Compute Annual operating costs

3. Compute Present worth of future operating costs and salvage value

4. Compute Life-cycle costs
Other considerations have been used in the award analysis, such as the delivery time, the warranty, and the capability of a supplier to handle the order size. The use of these considerations in the bid analysis is usually indicated in the proposed contract documents.

**VEHICLE ACCEPTANCE.** Many operators recommend inspections upon delivery before final acceptance. Inspections include test drives and visual examinations (37, 69). Appendix D contains a sample inspection checklist.

There are two major reasons for inspections. The first is to assure supplier compliance with the specifications in the contractual agreement. The second is that a number of vehicles have defects upon arrival. Fortunately, a majority of the defects are minor, and can be corrected by the operator. For example, poor workmanship has produced problems such as headlights which do not work, oil dipsticks which are not reachable, bolts which are loose, etc.

Repairing the vehicle in house or sending it back to the dealer or a local mechanic for repairs may delay its entrance into service. However, correcting defects upon delivery can avoid unexpected and more costly problems later on.

When the operator does not have the capability, inspections can be done by state agencies or a transit authority, by local agencies employing mechanics, or by local mechanics.

On-site inspections, having an inspector selected by the buyer to monitor the vehicles as they are being manufactured, has been suggested as a method to avoid vehicle problems upon delivery. However, not only is it costly, but it is not generally favored by suppliers and it does not always guarantee that a vehicle will be free of defects.

---

**funding sources**

Almost no public transportation systems are self sufficient through fares. To obtain revenue, systems draw from a variety of sources, such as:
- Trade membership dues
- Advertisement sales
- Contracting out services or equipment
- Individual contributions
- Volunteer labor (an indirect source).

Most systems, however, rely on Federal, state, and local governmental subsidies. Subsidies are particularly important for systems which are just starting a service and thus want to minimize financing costs, but which haven't yet built up capital.
FEDERAL. In 1977, the U.S. General Accounting Office identified 114 programs within 11 Federal departments which provide operating or capital assistance for transportation (105). The Department of Health and Human Services and the Community Service Administration handle a majority of these grant programs. Most of these programs designate the eligible passengers or the site to which passengers can be transported. Those sites are generally health, education, vocation, social service, or rehabilitation centers. These programs were designed to supply some type of social service, not transportation. The money allocated for transportation is intended to facilitate the clients’ access to these social services. Many of the programs do not provide capital assistance, providing instead assistance for clients to use existing transportation services.

Another major source of Federal funds is the Department of Transportation. Unlike the programs above, the primary intent of DOT programs is to assist in providing transportation. Within DOT, funds for nonurban areas (with a population of less than 50,000) are available from the FHWA. The money is administered under the Section 18 program of the Surface Transportation Assistance Act (98). Prior to 1978, when this section was enacted, nonurban areas relied mostly on social service grant programs and on UMTA’s Section 16(b) (2) program for capital assistance in transporting elderly and handicapped people (101). Section 18 marks the beginning of a Federal commitment to aid public transportation in nonurban areas.

Both capital and operating assistance is available through Section 18. Systems apply for funds through state governments, which are the initial recipients of this formula grant. Eligible recipients include public bodies, nonprofit organizations, and transportation operators. Private (for profit) providers are eligible, through purchase-of-service agreements with a local public agency, for the provision of public transportation services. The Federal government matches 50 percent of operating expenditures and 80 percent of capital expenditures.

UMTA, which is part of DOT, allocates capital assistance under Sections 3, 5, and 16 of the Urban Mass Transportation Act of 1964, as amended.

Section 3 is a discretionary capital grant program subsidizing state governments and local public bodies. Private transit operators may receive capital grant money by lease or by other arrangements from public agencies that receive UMTA grants. The Federal share of capital project costs is 80 percent.

Section 5 gives both capital and operating formula grants to public agencies through a state agency designated by each governor. Section 5 only disburses money to urbanized areas. Eighty percent of capital costs and 50 percent of operating costs of projects are granted.
Section 16 authorized UMTA to make capital grants to local, nonprofit agencies to meet the special needs of elderly and handicapped persons. Section 16(b) (2) allocates funds for capital assistance; applicants apply to UMTA through their state governments.

STATE. State governments are becoming more involved in assisting transportation services. Most states provide capital and operating assistance generated from general revenue sources (e.g., state gasoline sales, and property taxes). In addition, a number of states earmark for transit part or all of the proceeds of specific taxes (45). Some states pay all or part of the local matching share for Federal capital grants (45).

A recent study surveyed 25 states to examine the transportation assistance provided. (53). Twelve of the states reported no expenditures for capital assistance. Many of those states had laws explicitly preventing state funding for Federal programs. However, most states had made arrangements for channeling local funds to provide the non-Federal match for UMTA programs when the state was prohibited from owning vehicles or from providing capital assistance.

Most states use their capital grants assisting transportation to pay for buses. (45). With the Federal government paying 80 percent of capital project costs, the local matching amount required for bus replacement in most systems can be financed out of current funds rather than through state or local borrowing (45).

Many sources believe that the Section 18 nonurban public transportation program will encourage additional state involvement.

LOCAL. A recent study found that transportation systems using local funds tend to have a greater degree of local commitment, community control, and support than systems which rely solely on state and Federal support. (9)

Local public funds currently used for transportation services include property taxes, sales taxes, special district taxes, and other sources. Some localities also use part of their Federal formula block grants, such as the community development block grants and revenue sharing (52). However, rural communities having a population of less than 75,000 people rarely vote funds for generalized transportation (52). Nonurban areas receive a good amount of assistance from the Federal 16(b) (2) program, which provides nonprofit agencies with capital assistance for transporting elderly and handicapped persons. Unfortunately, many recipients do not budget for depreciation to plan for vehicle replacement and, in most cases, the local governments do not budget for this capital expenditure (53). Grant recipients tend to rely on future grants from the Federal (16) (2) program to provide 80 percent of the cost of a replacement vehicle.
IV OPERATIONAL CONSIDERATIONS

ONCE A VEHICLE has been selected and acquired, it is best to put it into service as quickly as possible. However, there are aspects of vehicle operation that should be considered before a vehicle is in service. Adequately preparing for vehicle-related costs, maintenance service, driver training, and insurance, can help to ensure an efficient and safe service.

financial considerations

COST ITEMS. There are many expenses associated with acquiring and operating small transit vehicles. Figure 21 lists many of the common cost items, dividing them between capital and operating costs. Capital costs are the purchasing costs for vehicles, facilities, and equipment needed to make a transit system operations. Operating costs include the day-to-day costs of running a system. (Figure 22 contains 1980 prices for vehicles.)

Depreciation deserves some comment here, because it is a controversial cost category. Many systems relying on Federal funds do not use depreciation in their cost accounting since they follow Office of Management and Budget Circular 74-4, Attachment B, which forbids the computation of depreciation on equipment paid for directly or indirectly by the Federal government. Proponents of the use of depreciation in cost accounting see two major advantages of a system recording depreciation:

- It permits systems to recover from other agencies that portion of their own vehicle which is used by other than their own clients (82).
- It could encourage the saving of money for vehicle replacement. (For further discussions of depreciation see References 82, 83, 54.)

It would seem that average expected costs applicable to all systems could be arrived at by examining and comparing the costs of several systems. However, these comparisons are difficult to make, particularly among social service agencies, due to (81)

*Prices vary according to the special modifications and options included in the vehicle package.
• Accounting variations, including:
  — Variations in accounting definitions
  — Variations in the coverage of accounts (e.g., some systems are not permitted to cover depreciation)
  — The exclusion of some transportation costs and the inclusion of non-transportation costs in transportation cost accounts;
• Operating data insufficient to permit evaluation and monitoring of system operations
• The difficulty of making comparisons between systems because of:
  — Differences in the time covered by data and accounts (e.g., because of inflation or other time-related cost differences)
  — Differences in the length of operating experience so that system averages may not be representative
  — Variation in the markets served (e.g., rural versus urban)
  — Variation in the type of service or service mix, and
  — Differences in vehicle type and vehicle mix between projects.

A recent study was conducted of the transportation costs of 56 systems serving elderly and handicapped people (83). These systems included social service agencies, transit properties, and agencies utilizing service contracts. It attempted to reconstruct costs and add missing costs to get comparable categories. The cost categories examined were:
  • Equipment depreciation
  • Overhead
  • Maintenance
  • Operating salaries.

The pie charts in Figure 23 show the percentage of the total cost that each category held.

Another way to look at costs is to convert costs based on time periods (i.e., monthly, or annual costs) to unit costs. Unit costs are useful in measuring and evaluating the operating performance of a system. The unit costs relevant to the evaluation and comparison of vehicles is the cost per vehicle hour and the cost per vehicle mile or vehicle kilometer. The operating (or total) cost per vehicle hour is equal to the total cost divided by the number of hours the vehicles were in operation. The operating (or total) cost per vehicle mile is equal to the total cost divided by the number of miles the vehicles have traveled. An evaluation of FHWA's Section 147 Rural Transportation Demonstration Project established probable ranges for costs of rural transportation systems (12). (See Figure 24.)
Figure 23. Transportation Costs of 56 Systems Providing Transportation for Elderly and Handicapped People
In urban areas, the cost per vehicle hour is a more useful measure than the cost per vehicle mile, because the operating vehicle may not actually be moving but may still be "in operation," (i.e., the vehicle is waiting in traffic, standing, or loading and unloading) (46). On the other hand, the cost per vehicle mile is useful in determining the effects of a change in the service level, or miles traveled.

**FACTORS WHICH AFFECT COSTS.** There are several factors which affect the vehicle operating costs:

1. **Type of Vehicle**
   Figure 2 shows how the cost per vehicle kilometer varies according to the type of vehicle. In addition, life-equipped vehicles cost more to acquire, require more fuel, and usually carry higher insurance costs (83).

2. **Age of the Vehicle**
   As the age of a vehicle increases, operating costs also increase (11, 102). Specifically, age has a significant effect on vehicle maintenance, but generally not on fuel economy (64).

3. **Traveling Speed and Operating Environment** (11)
   - Fuel consumption increases as speed increases.
   - Fuel consumption increases as the quality of the road surface decreases.
   - Costs for engine oil, tires and tubes, and vehicle repairs, increase as the quality of the road surface decreases.
   - Fuel consumption increases as the terrain becomes more hilly.

4. **Preventive Maintenance Program**
   An effective preventive maintenance program can help a vehicle run efficiently and avoid breakdowns and costly repairs.
5. Proper Vehicle Handling and Driving
A good driver can minimize accidents and vehicle wear. The U.S. Department of Energy in a Driver Aid and Test Project conducted from 1976-1978 found that trained drivers could increase the miles per gallon of a vehicle on the average by 10 percent (103).

6. Unionization of Drivers
Unionized drivers often have higher wages than nonunionized drivers (9,83,116). Labor contracts may require a full day's salary for drivers regardless of how many hours the vehicle is in operation. An evaluation of the LIFT program in Portland, Oregon determined that the allocation of driver hours based upon union work rules was 20 percent more than needed to provide the service (25).

7. Inflation
Costs for labor, equipment, oil, and fuel are rapidly increasing. Figure 25 shows, for example, increases in diesel fuel.

**SERVICE ARRANGEMENTS.** A complete maintenance facility for a transit bus consists of: (7)
- A storage garage
- A service area for daily fueling, cleaning and inspection
- A periodic inspection area
- A bus repair area
- A component unit repair-and-rebuild facility.

However, many of the systems which utilize small transit vehicles do not have a fleet large enough to justify the costs of, or the space needed for, a complete facility. In these cases service must be obtained outside the organization. Many systems have a maintenance operation which performs some routine work and minor repairs in house and which contracts out for major repairs. Figure 26 contains examples of work that may be contracted out.

Contracting out for service has the advantage of lessening the requirements for maintenance personnel, inventory control capability, shop equipment, and maintenance facilities (33). Another major advantage occurs with vehicle maintenance contracts which provide for periodic, lump-sum payments. In these cases an operator is permitted to budget fixed amounts for maintenance rather than make payments based on service received (63). This helps a system avoid cost overruns and cash-flow problems.
The fastest growing cost for bus transit systems in the last decade has been motor bus fuel. Most transit systems use No. 1-D diesel fuel, a highly refined middle distillate that minimizes air polluting emissions from buses. The cost of No. 1-D diesel fuel has risen 450% in the last nine years from 12 cents per gallon excluding taxes in 1970 to 65 cents per gallon excluding taxes in the summer of 1979.

This incredible price increase of diesel is five times as great as the Consumer Price Index which rose only 88% during the same time period. Because fuel costs are rising more quickly than inflation, they are becoming a much larger portion of transit system expenses.

In 1970 diesel fuel costs accounted for 2.5% of transit system budgets for motor bus operations. By the summer of 1979 diesel fuel accounted for 7.7% of the cost of motor bus operations. The rising portion of transit expenditures going to diesel fuel requires transit systems to economize in other areas to help prevent excessive cost increases while continuing to improve transit service to their communities.

Figure 26. Examples of Work That May Be Performed by Outside Agencies

- Heavy engine and transmission repairs/rebuids
- Air-compressor repairs
- Cylinder reboring
- Armature rewinding
- Crankshaft turning
- Bumper replating
- Radiator repairs
- Fuel-injector rebuild
- Radio repairs
- Air-conditioner repairs
- Fare-collection equipment repairs
- Paint work
- Body and upholstery repairs
- Brake reline/rebuild work
- Preventive and motor inspections and periodic servicing

Source: Reference 33.

On the other hand, having an in-house facility can have the following advantages:

- Vehicles get priority attention.
- Routine servicing can be scheduled more easily so that the transit service is unaffected.
- The operator can have quality control over the maintenance operation.
- It may be less expensive.
- Extra revenue can be generated if other agencies contract for the use of the maintenance personnel and facilities.

(See Figure 27 for the components involved in planning either option.)

PROVIDERS OF MAINTENANCE SERVICE. There are a number of different types of organizations which provide maintenance service. Following are examples of places where service can be obtained.

1. Private Garages and Gas Stations

Bids can be accepted for maintenance service by private garages. Some operators have kept costs down by receiving discounts from them. For example, the Regional Transportation Program (RTP) in Portland, Maine, received through its service contract: (21)

- A 10 percent reduction for labor costs
- A 20 percent reduction for parts
- Gas priced at only two cents over the wholesale cost.

Source: Reference 7.
RTP’s mechanic agreed, by contract, to these provisions, providing RTP obtained its regular services and all of its gas from him. RTP used specialty shops and other businesses for its major component (e.g., engine and transmission) repairs.

2. Dealers
Arrangements can also be made with the vehicle dealers. This has worked out especially well for warranty repairs. (43) However, this arrangement is usually only available for standard vans.

3. State or Local Agencies
Some agencies, such as state or county highway departments and school system bus contractors, have their own vehicle fleets which they service themselves or contract out to have serviced. Operators can join with these agencies and receive the service. Sometimes they also receive discounts on parts. For example, a group of organizations coordinated their purchasing and received a state discount number to purchase tires, batteries, anti-freeze, and other equipment from a supplier who handled the state highway department vehicles (12). This resulted in a 40 percent savings to the organizations.

4. Transportation Authorities
Some services are overseen by transit authorities and contracted out to an organization which operates the service. The contracting organization may handle maintenance.

Small system operators may contract with a transit authority for service. However, since most of the small vehicles are gas powered, transit authorities may not have the equipment or training necessary to service them (55). In addition, some operators have said that transit authority labor costs are higher than those of other businesses or system operators.

5. Other System Operators
Other system operators may have extra storage and/or service capacity which they contract out to gain additional revenue. Paratransit, Inc., for example, which runs a paratransit service in Sacramento, California, has approximately 20 non-profit agencies (about 100 vehicles) under contract for maintenance services. Paratransit, Inc. provides its customers with two contract options; one is a preventive maintenance program through which services are performed at predetermined mileage intervals for a flat monthly fee; the other is a fueling and safety-inspection agreement under which an agency purchases fuel and oil and is required to bring vehicles in for a safety inspection at specified intervals. A recent evaluation of Paratransit, Inc.’s program found that participating operators save on fuel, oil, labor, and parts (86). In addition, there are nonfinancial benefits to operators, including an improvement in the condition of the vehicles, the guaranteed availability of fuel during fuel shortages, and the consolidation of billing (coupled with
the ability of Paratransit, Inc. to carry outstanding balances). The Paratransit, Inc. service center operates without subsidy.

6. Coordination by System Operators

System operators can join together to coordinate their maintenance needs and select a common maintenance service provider. A coordinated maintenance service offers regularly scheduled preventive maintenance, nonscheduled repairs, emergency road service, and complete recordkeeping for vehicle performance and repairs (5).

The Community Resources Group (CRG) in Springdale, Arkansas, is an example of this type of coordination (18). CRG originally coordinated parts purchasing in order to get parts at wholesale prices. At present it also provides maintenance services. CRG claims that with 16 agencies participating in the joint purchasing and maintenance program they have saved about 51 percent in costs (106).

7. Local Schools

Some community colleges or vocational schools have training programs for maintenance personnel. A recent study reported that a system operator in Michigan found a maintenance agreement with a local community college technical-training program to be a cost-effective effort (12).

Another study reviewing innovative approaches to rural transport found two systems which used vocational schools. One of the systems, however, expressed dissatisfaction and switched to a local garage (63).

MAINTENANCE SCHEDULES. The common approach to maintenance scheduling is to assign inspection and servicing for different components on a vehicle at fixed mileage intervals (7). Scheduling regular maintenance inspections rather than waiting for breakdowns is called preventive maintenance.

There are several advantages to this system.

- Regularly scheduled maintenance improves learning, reduces labor costs, and lessens chances for error in maintenance.
- A parts inventory can be maintained with greater certainty, reducing the costs of procuring parts and improving bus down time (time a bus is out of service due to mechanical problems).
- A haphazard approach to maintenance contributes to poor vehicle performance and rapid deterioration (12, 55, 102).
- Breakdowns discourage passengers and can leave the driver and passengers stranded. Demand-responsive services are more adversely affected by on-the-road vehicle breakdowns than fixed-route services, which can compensate by lengthening headways (55).
A survey of transit systems revealed systems choose different mileage intervals for preventive maintenance (8). The differences in mileage were attributed to differences in the types of routes covered, the average distance between stops, the number of passengers carried, the road conditions, and traffic density.

There are innovative systems which attempt to tailor schedules for preventive maintenance to each vehicle, but these may require special equipment, such as on-board monitoring equipment in conjunction with periodic exams, or computer programs which can prescribe schedules (7,8).

An evaluation of the Westport, Connecticut Integrated Transit System recommended that an operator set up a preventive maintenance program before vehicle delivery since there can be “break-in” problems in the first few months of vehicle operation, during that time the public’s perception of system reliability can be strongly influenced (35).

In addition to scheduling maintenance at prescribed mileage intervals, preventive maintenance can be scheduled at prescribed time intervals. Examples of daily, weekly, and monthly inspections used by different operators are in Appendix D. Generally, the longer the time interval, the more detailed and comprehensive the inspection (i.e., a weekly inspection is more detailed than a daily inspection). Drivers are sometimes expected to perform these inspections, along with such minor services as keeping the vehicle clean and adding oil and other fluids. System operators may also rely on the drivers to report problems which need to be serviced. The conscientiousness with which drivers report problems early has been evaluated from maintenance repair records, as have the driving habits of the drivers.

Driver training

Driver training is used to achieve several goals:
- Good management and labor relations
- High quality service
- Safe service
- Cost efficiency.

The type of training a system chooses in order to achieve these goals depends on the type of service to be provided, the type of passengers, the funds available for training, the time available to free drivers from regular schedules, and the role the system managers want the drivers to have within the system.

There are several types of training:
- Driving maneuvers and defensive driving to prevent accidents
• First aid, cardiac-pulmonary resuscitation (CPR), and other emergency handling techniques
• Passenger relations, passenger assistance techniques, and sensitivity for elderly and disabled passengers (38,44,47)
• Handling of special equipment, such as wheelchair lifts (30)
• Basic maintenance and vehicle inspection to keep vehicles running safely and efficiently
• Driving techniques to save fuel and money (103)
• Recording of basic data for subsequent evaluations of service and vehicle performance.

Some systems and state departments of transportation have their own training programs and manuals (10,16,58). Other systems, particularly small systems, tend to use a form of on-the-job training in which a new driver observes a veteran driver for a week or so, following which the new driver drives while the veteran driver watches. However, regardless of the training program, new drivers are expected to take several months to become familiar with the service area (27,60,71). Special skills, for example defensive driving and first aid, are taught by local agencies such as the Highway Patrol and the Red Cross.

One of the major barriers to implementing a driver-training program is the money and time necessary to relieve a driver from service in order to attend training sessions. For example, a course called the Passenger Assistance Techniques (PAT), developed by a private consulting organization, has a 10-hour training session (100). The developers of this course believe that the feasible approach to driver time constraints is to train instructors who can in turn teach the course to their system's personnel. This was the approach used by a nationwide driver-training program sponsored by UMTA. Several regional training sessions were held in 1980. This training was designed for drivers of standard transit buses, but those involved with the course say drivers of small transit vehicles, particularly small buses, would find such training useful.

---

insurance

Insurance for vehicles has been a serious problem for many transportation providers. (See references 29,107,108,109,111). Systems run by transit authorities, and systems which can be included under the blanket coverage of state or local agencies, do not have difficulty. The systems which experience insurance problems are rural and human service agencies, particularly those which are just starting out. The major difficulties encountered by these systems are:
• Limited Availability — A restricted number of companies may be willing to insure the system.

• High Costs — There is a wide range in insurance costs per vehicle among systems and states. In addition, insurance is a high expense for many systems.

• Cancellation — Policies have been cancelled for reasons not always understood by the system.

• Restrictions — Insurance companies place restrictions on the systems' drivers, the charging of fares, the use of another system's vehicles, and the size of the geographical area in which the vehicle can operate.

Two major trends have brought about these problems. First, human service transportation providers are expanding into a public transportation role, and second, for-hire commercial transportation by private for-profit companies is being supplemented or replaced by government subsidized or operated transportation in rural areas. With these changes, the insurance industry is uncertain as to which legal doctrines of liability will prevail. The problem is further complicated by the lack of a sufficient actuarial data base.

These problems, however, are being addressed in a number of ways:

• The Insurance Services Offices of New York (a private nonprofit organization supported by the insurance industry) has filed two new programs which will be effective nationwide (106). The first program adopts a new form of insurance for social service agencies, intended to minimize uncertainty about rates. Rates are expected to fall between those for school buses and those for standard city buses. The second program provides additional liability insurance for vehicles owned by agency employees and volunteers which are used to transport agency clients.

• System operators are practicing risk management by instituting safety programs. These programs consist of driver selection and training, maintenance procedures, and claim procedures, all of which increase system safety.

• System operators may design a service in such a way as to avoid being classified in an expensive rating category. For example, a system may choose not to charge fares so as not to be classified as a for-hire service.
• Social service agencies and other operators can join together to purchase insurance as a cooperative. The Oregon Special Services Association is an organization large enough to have its own insurance broker. Membership by agencies is contingent upon their establishment of a safety program providing guidelines for driver selection and vehicle maintenance. Some of the members have experienced a considerable cost savings. (67). (See reference 119 for a further discussion of group insurance or self insurance plans.)

• State laws classifying transportation services by the standard of care required by the system while in operation, can be amended to state clearly the classification in which human service transportation belongs. This would decrease the uncertainty associated with claims and payments.
CONCLUDING COMMENTS

As the information for this report was being gathered it became apparent that what system operators most want to know is which vehicle to buy. For two reasons, however, that question can not be answered fully:

- The vehicles on the market are constantly changing.
- There is a lack of conclusive vehicle performance data.

Nor can that question be answered simply. These vehicles are required to provide a variety of service roles in different geographical areas. The information available with the current state of the art does not permit the designation of one vehicle for all users. Also, vehicle performance is determined not only by careful selection, but by other factors as well, such as maintenance procedures, operating environment, and vehicle handling.

This report presents a description of the types of vehicles available, and an overview of their operating history across the country. It also indicates that proper selection of a vehicle is only one consideration. Among others are the procurement process, which can be complicated and lengthy, preventive maintenance and repair, and financial questions.

It must be remembered that the rapid growth of transportation services requiring small transit vehicles is relatively recent. Thus, the state of the art will advance as system planners and operators gain and share their experiences.

GLOSSARY

accessibility
Freedom of a transit system from barriers preventing travellers from using that system.

bid
Statement of what vehicle a supplier will sell to the buyer and at what price.

body on chassis
Marriage of a light truck chassis and a body.

bond
Provides collateral against a bidder's failure to perform.

Caltrans
California Department of Transportation.

demand-responsive service
Characterized by flexible routing and scheduling to provide shared occupancy on demand, often with door-to-door service. Often provided for people whose mobility is limited.

DOT
United States Department of Transportation.

electrical vehicle (EV)
Vehicle with a conventional chassis in which the internal combustion engine has been replaced with an electric motor and a propulsion system powered by lead acid batteries.

feeder service
Provides transportation to and from a regular transit route.

FHWA
Federal Highway Administration.

fixed-route service
Transit service with regular routes and schedules.

life-cycle costs
All costs associated with a vehicle's useful life (i.e., acquisition, operating, and maintenance costs).

lift
Device which lifts a wheelchair user from ground level to the level of the vehicle floor so that the user can wheel onto the vehicle.

modified van
Standard van with some body and/or chassis modification.

paratransit
Flexible transportation service, operated publicly or privately. Typically, a small-scale operation using small transit vehicles.

pre-arranged ride-sharing service
Includes van pooling and subscription buses which operate mainly during peak time to provide commuters who have predetermined work schedules the opportunity to share vehicles.

preventive maintenance
Maintenance program based on regularly scheduled inspections rather than on emergency repairs necessitated by vehicle breakdowns.

seat kilometer (or seat mile)
Unit representing the number of kilometers (or miles) travelled by a vehicle multiplied by the number of seats in the vehicle.

shuttle service
Service which operates along heavily travelled corridors such as those in urban centers, large commercial mall areas, and airports.

small bus
Bus whose chassis and body are designed as an integral unit durable in transit service.

small transit vehicle
Vehicle smaller than the 40-foot standard transit bus.

standard van
Type of van available from automotive manufacturers.

technical specifications
That part of the contract which determines the actual components, construction, and performance requirements of the vehicles. Specifications can be phases or drawings.

cost per vehicle kilometer (or vehicle mile)
Equals the total system cost divided by the sum of the kilometers (or miles) travelled by each vehicle in the system.

wheelchair securement
Device which holds a wheelchair, and sometimes its occupant, in place within a vehicle. Also known as a wheelchair restraint or tiedown.

WHEELCHAIR SECUREMENTS

The manufacturers listed below are those who sell their devices as individual products. Manufacturers who only sell their devices as part of a vehicle package are not included. This list is not complete. We regret any omissions.

There is a great deal of variation among wheelchair securement devices. The devices are not only made of different materials, they also vary in their method of attachment to the vehicle and to the wheelchair. Therefore, the devices are grouped into the broad categories listed below. Although the photos of each type are of particular devices available on the market, they are used here merely to serve as examples and to illustrate the written descriptions.

BELTS

Belts used for securement devices are similar to car seatbelts. As securements, they are often attached to the vehicle by rings or tracks on the floor, or they are bolted directly to the floor. They are usually attached to the wheelchair at from one to four points on the chair frame. Some wrap around the chair (and passenger). Belts are often used to restrain the passenger as well as to secure the wheelchair. These belts are attached to the chair or vehicle, or both.

WHEEL RIM HOLDER

This device consists of rods or pins placed between U-shaped brackets or clamps. A securement system may include one or two rim holders. Some devices are semi- or fully automatic, which reduces the physical effort needed by the passenger to get into and out of the holder.

T-BAR

A T-bar is a horizontal bar placed between the wheels. Each end of the bar grabs onto the lower wheelchair frame, and a vertical rod or screw in the center of the bar attaches the bar to the floor.

LATERAL GRAB BAR

This device is a lateral arm which lies alongside the large wheels. It is often attached to the vehicle behind the wheels and grabs onto the front of a large wheel or onto the chair frame.

FRAME LOCK

A frame lock is a permanent wheelchair attachment which locks onto a device located in the vehicle.

OTHER

Devices were placed in this category if they could not be included in the other categories. Also, devices were placed here if there was insufficient information on their design.

BUS DAILY PREVENTIVE MAINTENANCE INSPECTION
AS REQUESTED BY 14243 OF THE CALIFORNIA ADMINISTRATION CODE, TITLE 5

BUS IDENTIFICATION

MAKE______ YEAR______ BUS#______ LICENSE#______ DATE______ MILEAGE:______

The daily preventive maintenance inspection by the operator shall include but not be limited to the following:

<table>
<thead>
<tr>
<th>O.K.</th>
<th>NEEDS ATTENTION</th>
<th>O.K.</th>
<th>NEEDS ATTENTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>□</td>
<td>Maintain water &amp; oil &amp; all vehicle fluid levels in accordance with the manufacturer's recommendations.</td>
<td>□</td>
<td>Check all tires &amp; lug nuts. If bus has hubcap, don't have to remove, just kick tire.</td>
</tr>
<tr>
<td>□</td>
<td>Check emergency exit &amp; all warning devices to determine if they are working.</td>
<td>□</td>
<td>Check lift operation.</td>
</tr>
<tr>
<td>□</td>
<td>Test horns.</td>
<td>□</td>
<td>Perform the following brake safety check:</td>
</tr>
<tr>
<td>□</td>
<td>Check driver's seat &amp; belts for wear and securement.</td>
<td>□</td>
<td>1. Test parking brake.</td>
</tr>
<tr>
<td>□</td>
<td>Determine that all doors, or emergency releases and windows are in operating condition.</td>
<td>□</td>
<td>2. Check brake pedal for brake adjustment.</td>
</tr>
<tr>
<td>□</td>

Weekly Maintenance Check

Van # ___________ Mileage ___________ Date ___________

1. Check and correct front suspension
2. Check and correct power steering lines
3. Check steering box mounting
4. Check fluid levels and correct
5. Check tire pressure
   Front _____ Rear _____ (90 PSI)
6. Inspect heater lines for chafing
7. Check all instruments and lights
8. Check seat mounting
9. Check front door operation and bracket mounting
10. Check lift operation and lift lock

**Mileage**

#### Special Instructions

For Repairs Needed

Preventive Maintenance Inspection Work Sheet

- Perform Monthly
- All Dart Vehicles

**Prepare for Inspection**

- Check Driver's Report
- Review Maintenance History

**Start Up and Drive (Check Operation Of):**

- Starting
- Parkin Brake
- Service Brake

**Remain in Vehicle (Check Operation Of):**

- Fuel Gauge
- Oil Gauge
- Battery Charging Gauge
- Windshield Washer & Wipers
- Steering Wheel Free Play
- Registration
- Head Lights, Hi Indicator
- Head Lights, Low
- Turn Signal, Indicators

**Outside Inspection (Check Operation Of):**

- Hood
- Bumpers, Body Damage
- All Lights
- Fuel Cap
- Front End, King Pins, Wheel Bearings, Tie Rod Ends

**Under Hood (Check Operation Of):**

- Air COMPRESSOR, MOUNTING & BELT TENSION
- Steering Gear & Shaft (Lube)
- Power Steering Hoses & Oil Level
- Throttle Linkage
- Water Pump & Fan Belt
- Water Pump & Fan Hub (Lube)
- C/CASE Breather, Clean/Change
- Air Filter, Change
- Exhaust System, Tighten
- Engine Oil, Change
- Oil Filter, Change

**Under Chassis**

- Engine & Trans. Mtg. Bolts Check & Adjust
- Body Mtg. Bolts Check & Adjust
- Transmission, Check Gear Oil Level
- Transmission, Check Cover, Bell & Seal Areas For Leaks

**Drive Off & Park**

- Engine Oil, Check Level
- Hood Latch, Check

**Comments**

- Wash Vehicle
- Transmission
- Horn
- Speedometer
- 4 Way Flasher, Indicators
- Interior Lights
- Instrument Panel Lights
- Heater & Defroster
- Air Conditioner
- All Window Glass
- Doors
- Seats
- Safety Equip.
- Outside Mirrors
- Wheels & Rims, Tighten Lugs
- Tires; Check Wear, Cracks and Pressure Record Lbs. Per Sq. In.
- Fuel Filter, Change
- Fuel Leaks, Correct
- Radiator, Check Level
- Radiator, Pressure Check
- Radiator, Clean Front
- Hoses, Check & Adjust
- Anti Freeze Protected
- Alternator, Belt Tension, Terminals, Check & Lube
- Battery, Check Water Level
- Battery, Clean Cables
- Master Cylinder, Fill
- Lubricate All Fittings
- Exhaust Muffler, Tail Pipe Hangers, Tighten If Loose
- Differential, Check Gear Oil Level & Clean Breather
- Differential, Check for Leaks
- Brakes, Adjust If Needed
- Springs, Shackles, U Bolts, Check for Cracks, Rust-Tighten

LEVEL A INSPECTION
(3500 MILES)

AGENCY __________________ VEHICLE NO. __________ MILEAGE _______ DATE ______

UNDERCARRIAGE

___ Check fuel tank lines for leaks
___ Check differential for leaks
___ Check rear springs, shackles, and shocks
___ Check driveshaft center support and u-joint
___ Check transmission for leaks
___ Check shift and clutch linkage
___ Check front suspension and shocks
___ Check steering linkage
___ Check exhaust linkage
___ Lubricate

BRAKES

___ Check brake lines for leaks or checking
___ Check brake vacuum hoses
___ Check brake adjustment
___ Check brake pedal clearance
___ Check emergency brake

UNDERHOOD

___ Pressure test cooling system
___ Check coolant/antifreeze level
___ Check cooling system circulation
___ Check brake fluid level
___ Check power steering fluid level
___ Check battery and cables
___ Check starting and charging system
___ Check windshield water fluid

___ Check tire wear
___ Check for nails, glass, etc.
___ Check for tread separation
___ Check air pressure
___ Check lug nuts for tightness

TIRES

___ Check all fuel lines and connections for leaks
___ Check all belts for looseness or signs of wear
___ Check all hoses for leaks or signs of wear
___ Check for loose wiring or vacuum lines
___ Check air filter--clean
___ Check accelerator linkage
___ Change oil and filter

ENGINE

___ Check for loose body bolts

BODY INTERIOR

___ Check first aid kit
___ Check fire extinguisher
___ Check seats for tears and looseness
___ Check floors for tears or loose wheelchair track
___ Check fare box for secureness
___ Check emergency exit
___ Check window operation
___ Check rearview mirror
___ Check windshield wiper blades

BODY EXTERIOR

___ Check all windows
___ Check sideview mirrors
___ Check attached body parts for looseness
___ Check windshield wiper blades
___ Check for loose body bolts

IGNITION ANALYSIS

___ Check firing voltage (secondary circuit)
___ Check reserve voltage (isolate coil)
___ Check fuel filter
___ Check timing
___ Check idle and adjust carburetor

ACCESSORIES

___ Check heater output
___ Check air conditioner output
ROAD TEST VEHICLE

_____ Check acceleration
_____ Check braking
_____ Check rattles, noises
_____ Check steering freeplay and drift

APPENDIX E
OUTLINE FOR WRITING TECHNICAL SPECIFICATIONS

[E.1] Writing a Specification
This chapter will provide the how of writing a set of technical specifications. As you read through this, keep in mind that each contract is different from the last one and will contain variations that you will need to work out. Always remember that any specification should cover all the materials and circumstances that are peculiar to a given project. It becomes very important that you screen all written materials carefully...

What is a "Technical Specification"?
The "Technical Specifications" in a set of Contract Documents represent the "contractual-technical" portion of the Contract Documents. Its purpose, in most situations, is to "define the quality and types of workmanship and materials upon which the Contract is Based." For some contracts, such as for the purchase of equipment, the Technical specifications may replace at least some of the functions of drawings, which are used to "define the physical relationships of materials upon which the Contract is based.

Where do You Begin?
The first step is to decide what you want. List informally the features you desire on the Transbus, prepared by UMTA. The body of the specifications was arranged in logical order, which could be carried over into the final specification. A checklist of possible items, possibly from another set of technical specifications, may be used so you can avoid overlooking some category that needs to be included. An example of such an arrangement can be seen in the Technical Specifications for the Transbus, prepared by UMTA. The body of the specifications was arranged in the following manner:

- Body (of the bus)
  - Shell
  - Operating components
  - Interior trim
  - Windows
  - Insulation
  - Ancillary features

- Chassis
  - Propulsion system
  - Final drive
  - Suspension
  - Steering
  - Brakes
  - General chassis
  - Interior climate control
  - Radio and public address

The arrangement is logical and could easily be expanded into a full set of specifications (as was done). All that is needed to complete the technical specifications is a format.

What Format Should You Use?
Only one format will be suggested — one that is similar to the [Construction Specifications Institute] (CSI) format. It is suggested that you arrange your Technical Specifications into three parts, similar to the one used by CSI. The three-part format would look like this:

Part 1: General
Part 2: Product
Part 3: Execution

Part 1 encompasses certain aspects of the project requirements that are often included in the General Conditions. However, they belong with the Technical Specifications, because they pertain particularly to the Product...

The section on the Product completely describes what is to be provided by the Contractor, whether equipment or services. The more complete your description of the product, the more likely it will be that you get what you want at a good price. Do be careful not to specify the product in too much detail, because that may limit the number of bidders more than you wish to.

Part 3, Execution, covers what the Contractor does. With the exception of service contracts, the specifications are for products produced in the manufacturer's plant and delivered to the buyer in accordance with a specific schedule. Since the work is done on the Contractor's property, the buyer is not responsible for injuries. Therefore, the only execution requirements for equipment have to do with pre-delivery and post-delivery inspections...

Of course, for service contracts, execution is the most important factor in the Contract, so this could be the largest of the three parts.

[E.2] Sample
A sample outline for a mythical set of Technical Specifications follows. Examine the sample as you develop your own specifications. It should be helpful.

Technical Specifications for ____

Part 1: General

Scope
(Describe what this specification is all about.)

Items Covered by These Specifications
The specifications which follow...

Overall Requirements
(Include all the basic criteria here. Details such as physical size and weight, capacity, range, service life, accessibility for repairs, and interchangeability need to be discussed.)

Items not Covered
(Describe all such items, tell who is to furnish them and how. Avoid use of "...by others" if it will be furnished as part of this contract.)

Definitions
(Define any terms not normally used, but used here. Just don't get carried away and list too many.)
E-2

Applicable Regulations

Safety Requirements
(List requirements of local, state, or Federal laws which must be met while performing the services, or which the equipment must meet under normal use.)

Pollution Requirements
(Use when applicable. This could refer to emissions, disposal of waste, etc., occurring during the performance of services or when the equipment is in use.)

Quality Assurance

Production Quality Control
(Insert a standard paragraph here, describing function and lines of responsibility. Refers mainly to production of equipment, though could be retitled and rewritten for use with a service contract.)

Organization Function
(Include range of responsibilities, including a note on how quality assurance will be achieved on supplied parts.)

Records
(Describe marking requirements for inspected items, test-data retention and availability.)

Measuring and Testing Facilities
(General comments on measuring and testing devices, plus use of standards for calibration.)

Inspection
(Note the need for a system used to keep track of status of inspection and documentation of same.)

Warranty
(General statement on requirement for warranty from Contractor.)

Guaranty
(Statement will vary according to what is to be furnished. Express in terms of miles, time, or whatever is appropriate.)

Detection and Repair of Defect
(Describe how a defect is to be corrected, [should there be one] how parts are to be supplied, and who pays.)

Reimbursement for Labor
(Should the Public Agency incur any costs, tell how the Contractor will reimburse. Be sure to include fringe benefits and overhead costs.)

Engineers/Technical Assistance
(When you get new equipment, there may be problems. You may need some technical assistance.)

Spare Parts
(The Contractor must assure you of access to spare parts. Specially made parts can be expensive.)

Warranty after Replacement/Repairs
(A statement needs to be made about the continuance of the warranty after a defect has been corrected.)

Part 2: Product (the Transbus Specifications were chosen for this example.)

Body

Shell

Operating Components
A. Doors
1. Control
2. Closing force
3. Actuator
4. Emergency operation

Interior Trim
Windows
Insulation
Ancillary Features

Chassis

Propulsion System
Final Drive
Suspension
Steering

Buses
General Chassis
Interior Climate Control
Radio and Public Address

Part 3: Execution

Pre-delivery Tests
(Describe how the tests will be done, by whom, and [include] something on documentation. If the Public Agency is to witness the tests, state how the arrangements will be made.)

Post-delivery Tests
(Provide for method and time limits applicable for the Public Agency to complete the tests.)

[E.3] Final Form
Take the outline, once it is complete, and write up the details . . . You may be tired of writing by now, but it is a good idea to go over them thoroughly once again to be sure that there are no conflicting provisions and that the statements made reflect your desires adequately.

E.4 Outline Specifications for Transit Services
Part 1: General
Scope

Items Covered by these Specifications
The specifications which follow describe the services to be furnished under this Contract, including performance standards, non-performance measures, and control of the project, including accounting requirements.
Overall Requirements
Work covered by these specifications includes the furnishing of buses, drivers, and all associated supplies and services necessary to provide the following scheduled transit services:
(Here list the services desired.)

Items not Covered
The Public Agency shall furnish all other equipment and services necessary for the operation of the proposed transit services. Those items of equipment and services include, but are not limited to, the following:
(Here list the services/equipment furnished by the Public Agency.)

Definition
The following definitions of terms shall apply:

Small buses - Buses with a minimum rated capacity of 16 persons
Medium buses - Buses with a minimum rated capacity of 20 persons
Large buses - Buses with a minimum rated capacity of 45 persons

Applicable Regulations
Safety Requirements
Contractor shall comply with all applicable federal, state, and local laws and regulations covering transit equipment, driver education and licensing, and driving performance. These include:
(Make a list.)

Pollution Requirements
Exhaust emissions from transit equipment used in the performance of the transit services covered by this contract shall not exceed the following levels:
(Here list the regulated components of the exhaust emissions and the required maximum levels.)

Quality Assurances
Organization Function
The Contractor shall provide an adequate number of personnel within his/her organization with the authority and responsibility to assure driver and equipment performance standards as specified in these documents. The quality assurance organization shall be directly responsible to the Contractor’s top management.

Quality of Services
The quality assurance organization shall have the following minimum functions:
1. Verify adherence to the time schedule.
2. Ensure that safe driving practices are observed.
3. Check that operating personnel maintain a neat and clean appearance and treat passengers with courtesy.
4. Require that transit equipment is clean and in good operating condition.

Records
Inspection records shall be maintained and made available to the Contracting Officer for his/her inspection.

Part 2: Products

Equipment Furnished

Transit Buses
(List the number and types of buses required for the services, plus any requirements for optional equipment — such as air conditioning.)

Condition of Equipment
(If you wish to establish any standards of equipment cleanliness or operating conditions, this would be the place to make those statements.)

Part 3: Execution

Performance Standards

Time Schedule
(Describe the time schedule to be followed by the buses and any deviations allowed.)

Service Standards
(Here make any appropriate statements regarding state of bus operator training, adherence to standards of safe driving, and such indicators of good customer service as courtesy, appearance of bus operator.)

Financial Records

Accounting Requirements
(Establish the Contractor Accounting requirements here that will enable you to meet your accounting commitments in connection with your contract with the Public Transit Division.)

Revenues
(Provide for the disposition of all funds collected by the Contractor in connection with the services provided under the Contract.)

Audit
(State that the Contractor shall permit you, the Public Agency, and/or the Public Transit Division to perform an audit of records connected with the project.)

APPENDIX F
LIFE-CYCLE COSTING METHOD

Although the total operating costs of a vehicle are from one-and-a-half to two times the cost of its purchase, only a few municipalities evaluate both operating and purchasing costs (i.e., life-cycle costs) when selecting a vehicle. For the municipalities that currently consider only the lowest bid price, a life-cycle costing model is provided in this appendix which can be formally or informally adopted as a guide to procurement decisions.

A formal use of the model ... requires that bid proposals from competing suppliers incorporate estimates of vehicle operating costs as well as the purchase price. In this case, the municipality would have to specify exactly which costs were to be estimated by the bidder, mindful of two potential pitfalls. First, if the costs of a particular aspect of owning the vehicle are somewhat uncertain (e.g., maintenance costs), the bidder is likely to inflate the cost element above the cost that could reasonably be expected. Second, potential legal challenges to contract awards require that cost estimates have a sound basis in fact. While the Environmental Protection Agency (EPA) mileage ratings ... provide such a basis in the case of fuel costs, estimates of maintenance costs are likely to be more subjective. Eventually, additional Federally mandated product specifications will provide a more suitable legal basis for formal life-cycle cost bidding.

Municipalities may find that an informal application of life-cycle costing is more appropriate from both legal and economic standpoints. Such an application ... involves an in-house life-cycle cost analysis to establish a set of narrowly defined vehicle performance criteria necessary to remain below an acceptable life-cycle cost ceiling. For example, the formal bid specifications could establish an average EPA-based miles-per-gallon standard assuming 60 percent city and 40 percent highway driving and a gross vehicle weight ceiling for acceptable bids. The list of specifications could be expanded to include many of the items mentioned in this report.

Even partial life-cycle cost analysis which considers only the fuel and purchasing costs provides a truer picture of the total owning cost of a vehicle that does the initial cost alone. The life-cycle costing model that follows can be as simple or as complex as the cost information ... available to the reader allows ... The reader may use these costs in the analysis if local data [are] unavailable.

LIFE-CYCLE COST MODEL

The life-cycle costing methodology presented below consists of the four essential steps ... Instructions and worksheets are provided, and a sample analysis is included.

Step 1: Collect Necessary Data

The life-cycle cost of a vehicle includes the purchase price, the total costs of fuel, maintenance, and insurance, as well as any other costs which may be associated with ownership.

The resale value of a vehicle at the end of its life in the fleet is a value rather than a cost and should also be included in the analysis. To compute the life-cycle cost, it is useful to assemble all of the relevant and available information used in the analysis; Worksheet [1] is provided for that purpose. Note that some of the items of information in the Worksheet are optional, which means that a satisfactory analysis can be performed without them, although the results of the analysis will be more accurate if all costs can be estimated.

This section defines the data elements ... required to analyze the life-cycle cost of a vehicle, and suggests sources of information for obtaining or estimating [them]. The elements to be defined are listed in Worksheet [1] along with a summarized list of information sources.

Required Data Elements

The first seven elements listed in Worksheet [1] are essential for compiling a basic life-cycle cost analysis.

1. Purchase Price: The purchase price of the complete vehicle, including all optional equipment, dealer preparation, and delivery, should be available from the local automobile or truck dealership.

2. Expected Annual Mileage: The anticipated usage of the new vehicle can be determined from historical data on the vehicle(s) it will replace. Only ... estimated mileage is required, not a precise value ...

3. Number of Years the Vehicle is to Remain in the Fleet: The anticipated life of the vehicle in the fleet can be estimated from historical data or by the appropriate department head.

4. Expected Resale Value: The salvage value of the vehicle when it reaches the end of its lifetime in the fleet can be estimated by department heads based upon their experience. If vehicles are typically held until fully depreciated, a salvage value of zero may be assumed.

5. Acceptable Discount Rate: To recognize that procurement funds could be diverted to other investments with a positive return, it is common practice to "discount" all expenses to their present value. The selection of a discount rate is a local policy decision, although it is recommended that the rate be set at least as high as the level of interest rates available in savings bank accounts.

6. Fuel Economy of the Vehicle in Miles Per Gallon: The fuel economy of new passenger cars and trucks is rated by the EPA. These ratings may be used directly, or modified to reflect past experience in fleet fuel economy ...

7. Price of Fuel: [This is] the current price of fuel per gallon to the municipality ...

Optional Information

The seven elements listed above are sufficient to complete a basic life-cycle cost analysis. It is to the advantage of the municipality, however, to consider as many of the total vehicle-owning costs as possible. If the three optional items listed in Worksheet [1] can be included, a more accurate and complete estimate of the actual life cycle cost can be made.
8. **Estimated Annual Maintenance Cost**: [This includes] charges for labor and parts, and may be estimated from the repair records of similar vehicles in the fleet.

9. **Annual Insurance Cost**: The estimated cost of insuring the vehicle should be based on past experience with similar vehicles.

10. **Other Miscellaneous Annual Costs**: Any special, recurring costs which may apply to specific vehicles, including the operating costs associated with optional equipment, such as [that] described in the manual sections on vehicle procurement, should be included.

**Step 2: Estimate Annual Operating Costs**

The annual operating cost of a vehicle can be estimated using the information from a completed Worksheet [1]. To facilitate the computation of this estimated cost, Worksheet [2] provides a step-by-step calculation procedure. Simply follow the sequence of instructions to arrive at the annual operating cost in line 9. If one or more of the optional costs from Worksheet [1] (lines 8-10) have not been estimated, enter them as zeros in Worksheet [2].

**Step 3: Determine Present Value of Future Operating Costs and Salvage Value**

Using information from Worksheets [1] and [2], a discounted operating cost is calculated for the entire life of the vehicle in the fleet. Using Worksheet [3], the discounted salvage value of the vehicle is then deducted from this cost to arrive at a net vehicle-operating cost. Follow the sequence of eleven instructions in Worksheet [3] to perform these calculations.

**Step 4: Compute Life-Cycle Cost**

The life-cycle cost of a vehicle is the sum of the purchase price and the net vehicle-operating cost, as calculated in Worksheet [3]. When comparing two or more competing bids for municipal vehicle purchase, the life-cycle costs of each alternative should be compared directly and the lowest selected, unless one of the alternatives has been considered for a different lifetime in the fleet. If this occurs, the life-cycle cost of each alternative should be divided by its assumed lifetime to arrive at an average annual life-cycle cost. These averages can then be compared, with the lowest alternative being selected for purchase.

Worksheet [4] is provided to guide the reader through the final step of calculating the life-cycle cost of a vehicle using the purchase price and assumed life from Worksheet [1], and the net vehicle operating cost from Worksheet [3].

**LIFE CYCLE COST**

**AVERAGE ANNUAL LIFE CYCLE COST**
This appendix contains basic design specifications of small transit buses. Although the focus of this report is small transit vehicles, it is useful to have information about all sized vehicles when choosing a vehicle. See: New Bus Equipment: An Overview of the UMTA Program to Introduce Innovative Transit Buses, January 1981, UMTA-MA-06-0013-80-1
In the small bus category are heavy-duty transit buses under 35 feet in length with seating capacity for 15 to 35 passengers. During the 1970's, utilization of these vehicles increased dramatically in small urban areas where ridership is lower. These smaller transit vehicles are used for special needs, subscription, charter, airport/mall shuttle, and feeder services.

This appendix contains examples of small buses which are currently available, or which manufacturers claim are at an advanced stage of production design and could be purchased or leased in quantity within the near future. The examples are intended to be representative and do not constitute a complete list of available vehicles.
Bluebird claims that its Citybird 2904 has been developed using the best available basic components in a straight-forward design. In keeping with this design philosophy, the Citybird has a rear diesel engine contained in a “cradle mounted” assembly with the transmission, radiator, and exhaust systems. The manufacturer maintains that the complete assembly can be withdrawn from the vehicle and refitted in four hours. Standard features include air ride suspension, air brakes, integral power steering, full open sliding windows, and air conditioning. Sales, warranty, service and parts are handled directly by the Bluebird factory in an attempt to remain easily accessible and responsive to operators. Each purchaser of Bluebird units is entitled to send two service personnel to a factory-sponsored, 40-hour maintenance school. The Bluebird Body Company estimates the Citybird’s lifespan to be 10 to 12 years.

The Chance RT-50 is a heavy-duty small bus which adheres to large bus design practices. As a result, air brakes, air suspension, and a diesel engine are standard. Advanced bus design features such as low floors and extra large side windows are also incorporated into the design and the double-wide entrance/exit doorway is standard equipment. Aircraft-type fasteners are used on the skirt panels to facilitate expedient replacement. The manufacturer claims that support components have been selected to meet strict requirements for quality and market availability. The standard configuration includes a front-mounted engine, 12/24 dual-voltage electrical system featuring quick disconnect sectional harnesses, color-coded air line system and semi-pneumatic anti-ride bumpers. A drive line brake retarder by Telma is optional. The manufacturer’s estimate of lifespan for this vehicle is 10 to 15 years.
DESIGN SPECIFICATIONS

Dimensions
- Length: 26.5 ft.
- Width: 96 in. (excluding mirrors and opened doors)
- Height: 120 in. (overall)
- Wheelbase: 168 in.
- Turning Radius: 28.5 ft. (from outside body corner)

Passenger Capacity
- Seated: 25 passengers
- Standees: 15 passengers

Curb Weight: 14,500 lbs.
Gross Vehicle Weight: 22,000 lbs.
Tire Size: GVR 9 x 22.5 tubeless
Propulsion System: Caterpillar Diesel 3208-175 (V8)
Suspension: Air
Passenger Windows: 5 fixed and 4 sliding
Air Conditioning: Standard - Thermo King BI-M15
Floor Height: 32 in. (at kneeled position - 29 in.)
Step Height
- Ground To First: 14 in.
- First To Second: 9 in.
- Second To Floor: 9 in.
Door Opening Widths (Clear Openings)
- Front: 48 in.

The Citycruiser T-30 is a small heavy-duty transit bus designed specifically for mass transit operations. Included as standard equipment are air suspension, heavy-duty air brake system, rear mounted diesel engine, power steering, tilt steering wheel, rear vertical exhaust, 90-gallon fuel tank, three-way adjustable roof ventilators, and double-glazed windows. A test circuit is provided on the control panel to verify operation of all telltale warning lights. A wide variety of seat styles and configurations is also available. The rear axle has wide spaced air springs for added stability. The front door is of the one-piece type, providing superior sealing capabilities against weather. The rear exit features a "sensitive treadle" controlled by a driver's lock mechanism that opens the door when a passenger stands on either step. Field technical representatives are available for troubleshooting.

SMALL TRANSIT BUS
Skillcraft Transmaster L31

The Skillcraft Transmaster L31 is a small diesel-powered heavy-duty transit bus designed to meet UMTA's 1976 small bus performance specifications. The Transmaster features a low floor that incorporates a manual wheelchair ramp as standard equipment. This driver-operated ramp maintains a 14° angle to the ground and an 11° angle to a 9-inch curb. The engine and transmission are mounted side-by-side, coupled with a special transfer case. This engine mounting design has been combined with a very large engine compartment, resulting in a high degree of maintenance accessibility. Consequently, Skillcraft claims that down time required for normal repair and maintenance procedures is reduced by 15 percent. A dual visual-audio diagnostic driver's instrumentation panel is also provided. The Transmaster uses a single door in its standard design. However, a version with an additional door and reduced seating capacity is available as an option. Manufacturer's estimated lifespan for the vehicle is 12 to 15 years.

SMALL TRANSIT BUS
Steyr City-Bus

The Steyr City-Bus is a small transit bus which uses front wheel drive and thus allows a continuous 12-inch low floor. Its low floor, standard driver-operated manual wheelchair ramp, and standard 49-inch clear door opening indicate that this vehicle has been designed to facilitate transit service for the mobility impaired. The manufacturer claims that the front wheel drive, combined with four wheel independent suspension gives the Steyr City-Bus extra handling ability in snow. The engine transmission assembly is front mounted to the vehicle by only three bolts, facilitating easy removal. Steyr maintains that this engine will achieve 15 to 16 miles per gallon and estimates the vehicle's lifespan to be 10 to 12 years. The body is constructed of laminated fiberglass.
