Speed Improvement Study

Restoration of Historic Streetcar Service in Downtown Los Angeles

Small Starts Speed Improvement Analysis
Technical Memorandum

Executive Summary

A Small Starts Speed Improvement Analysis has been performed to evaluate potential physical and operational treatments that would improve the run time of the Downtown Los Angeles Streetcar Project. The table below summarizes the results for the afternoon peak hour (worst case condition).

Streetcar Run Time Analysis Results

	Existing	Baseline	Scenario 1	Scenario 2	Scenario 3	Scenario 4
Description	Without Improvement (AECOM Estimate)	EIR Assumed 3 Protected Turn Phases	Additional Improvements at 16 Locations	Scenario 1 + Transit-Only Lane (2 SB Lanes)	Scenario 1 + Transit-Only Lane (1 SB Lane)	Scenario 1 + Stop Reduction (25 to 16)
Travel Time	49.5 min	45.8 min	38.5 min	38 min	37 min	34 min
Speed	4.7 mph	5.0 mph	5.9 mph	6.0 mph	6.1 mph	6.7 mph
Approx. Ridership (7th with Grand Ave)	4,400	4,800	5,700	5,700	5,700	5,400

The existing run-time estimate performed by AECOM added two minutes of delay adjustment and did not have the benefit of protected left turn signal phases at 7th and Hill and 1st and Hill. HDR's run-time estimate spreadsheet was modified with intersection delays calculated by Syncho.

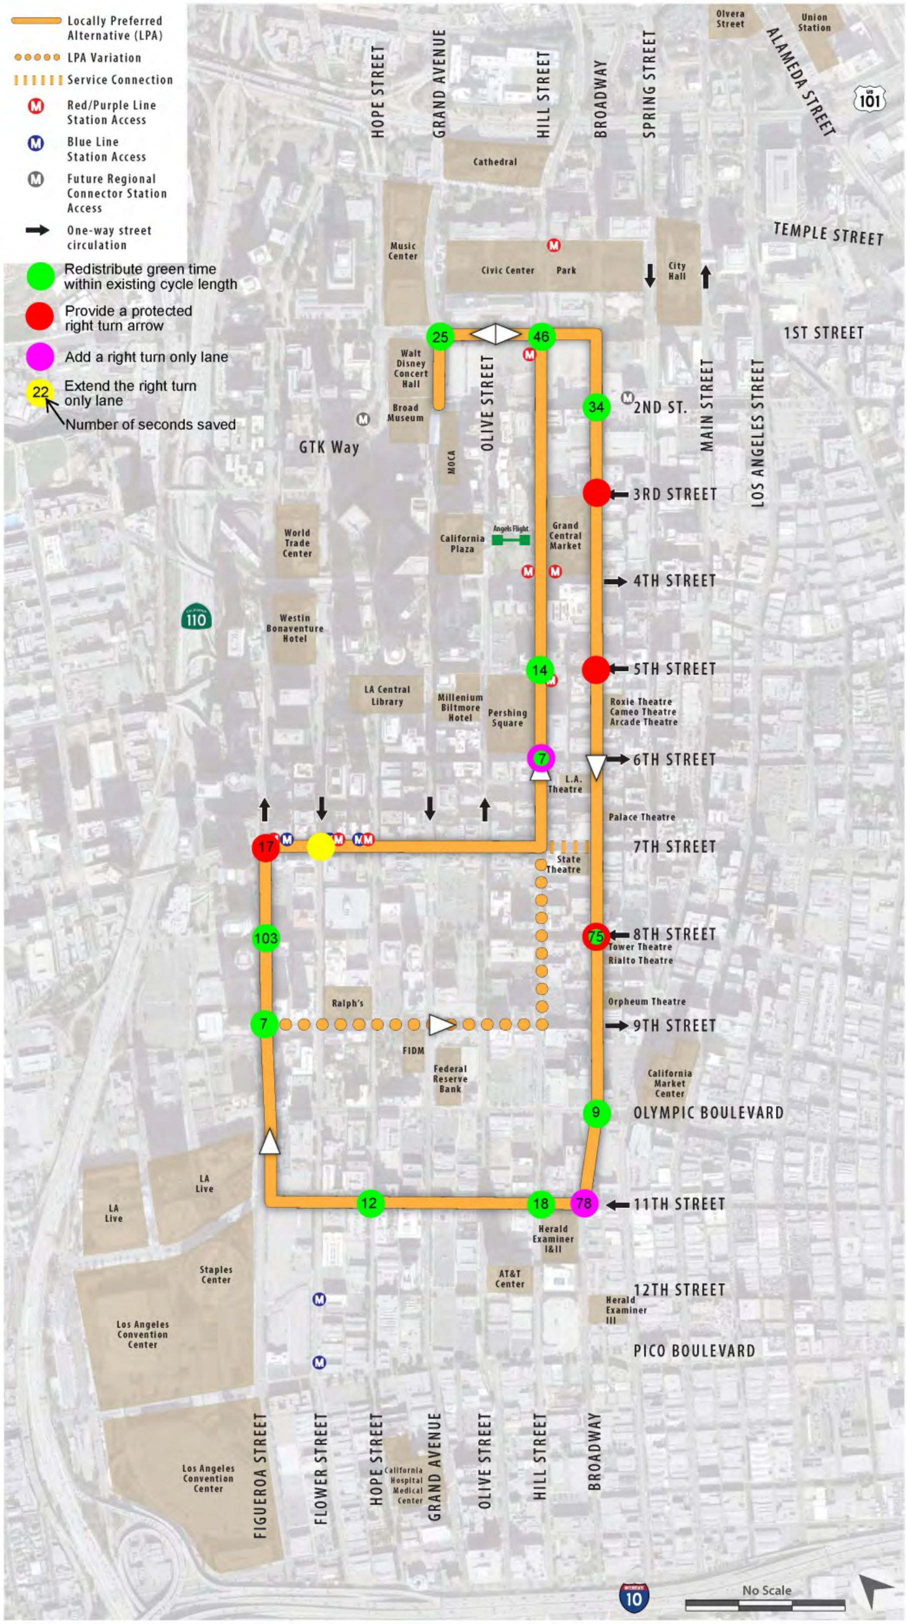
Scenario 1, redistributing 5 to 15 seconds of green time at 11 intersections, providing a protected right turn phase at 4 intersections, extending the right turn lane at one location, and providing new right turn lanes at two locations, saved seven minutes of run time, and got within 3.5 minutes of the 35 minute run time goal. The map on the next page shows where the Scenario 1 improvements are proposed and the resulting run time savings.

Scenario 2, adding a second lane southbound on Broadway with one of the two lanes being transit-only, saves 34 seconds of run time compared to Scenario 1.

Scenario 3, converting the one southbound lane on Broadway to transit-only, saves 90 seconds of run time compared to Scenario 1, but causes significant traffic impacts at six intersection locations.

Scenario 4, reducing the number of streetcar station stops from 25 to 16, saves 4.5 minutes in run time compared to Scenario 1. Combined with the proposed Scenario 1 modifications, Scenario 4 achieves the goal of a run time of less than 35 minutes. However, a ridership estimate was performed by Metro with the reduced number of streetcar station stops, and the result was a reduction of 300 boardings per day, from 5,700 riders to 5,400 riders.

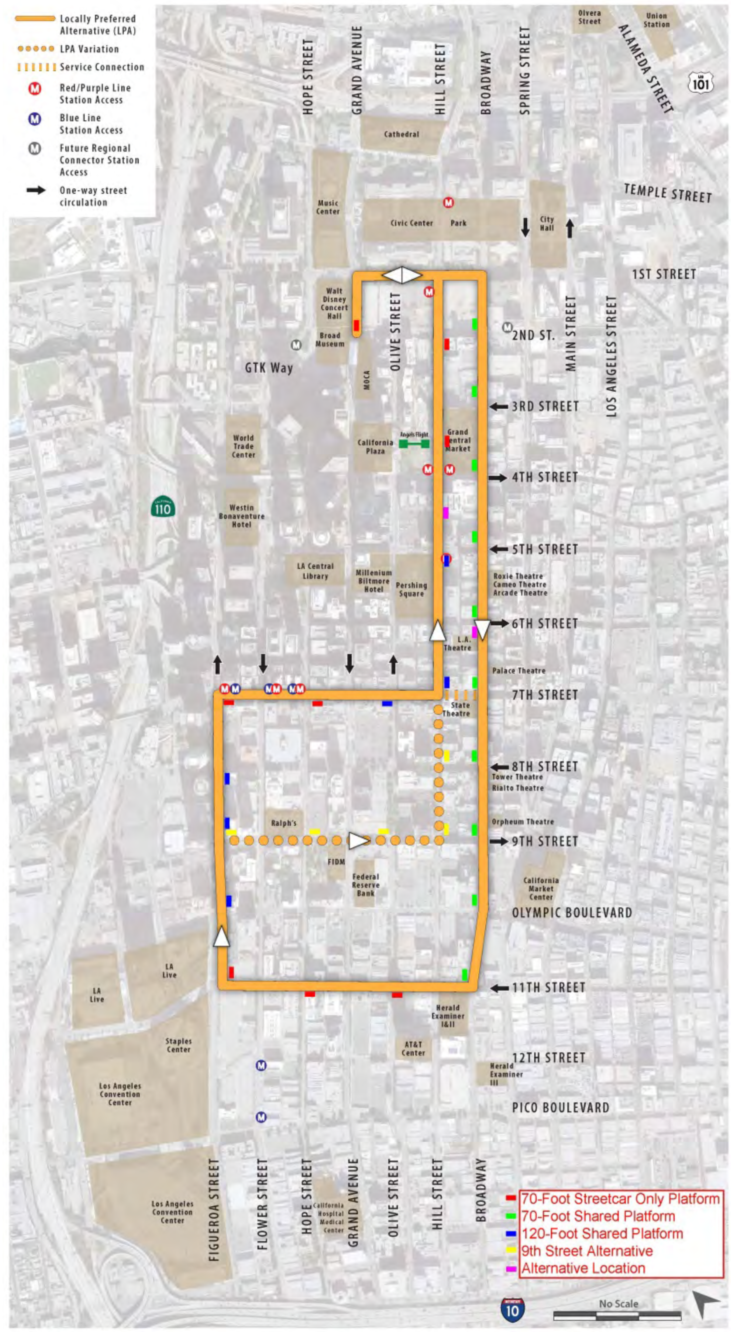
Scenario 1 Improvements



September 25, 2015

Introduction

The Downtown Los Angeles Streetcar (Project) is a 3.8-mile loop that starts in an exclusive median on Grand Avenue just north of 2nd Street. It turns right on 1st Street, turns right on Broadway, turns right on 11th Street, turns right on Figueroa Street, turns right on 7th Street, turns left on Hill Street, turns left on 1st Street, and turns left on Grand Avenue back to the starting point. There is variation to the locally preferred alternative (LPA) that uses 9th Street that will also need to be considered in the environmental document.



The Project is seeking FTA funding for the construction and project development costs through the Federal Transit Administration (FTA) Capital Investment Grant Program. The FTA will evaluate the project against six Project Justification Factors (Mobility Improvements, Environmental Benefits, Congestion Relief, Cost-Effectiveness, Economic Development, and Land Use), and overall the Project must receive at least a medium rating in order to receive funding. The critical elements of this evaluation are ridership, capital cost, and operations and maintenance (O+M) cost.

Ridership has more impact on the overall rating than any other factor because it affects three of the six justification factors. FTA requires all of its projects to estimate ridership using a software program that they have developed called STOPS (Simplified Trips on Project Software). When the project is submitted to FTA for a rating, it will need to have a ridership estimate, a detailed operating plan, and proposed physical improvements that are all consistent with one another. In addition, the FTA will be the lead agency for NEPA clearance, and the environmental document will have to be consistent with each of these other elements. The FTA will need evidence and documentation to back up the estimated run time for the transit service, because this affects the ridership and determines the number of streetcar vehicles that will need to operate to achieve the planned service headway. The FTA will be checking the capital cost estimate to be sure that the correct number of vehicles is included in the project capital cost estimate, that the O+M estimate reflects all of these vehicles in service, and that the MSF facility is sized appropriately to accommodate the vehicle fleet. The run time is a critical factor for the project.

As part of the Alternatives Analysis, in 2011, the project team prepared operating plans and O+M estimates for the seven alignments being evaluated as part of the final screening. For the two alternatives that were selected as the LPA, the streetcar run time was estimated to be 35.5 minutes, requiring 6 vehicles to meet the peak 7-minute headway plus one spare. This equates to an average speed of 6.5 miles per hour (MPH). The estimate was based on 25 stops at 2nd/Grand, 2nd/Broadway, 3rd/Broadway, 4th/Broadway, 5th/Broadway, 6th/Broadway, 7th/Broadway, 8th/Broadway, 9th/Broadway, Olympic/Broadway, 11th/Broadway, Olive/11th, Hope/11th, 11th/Figueroa, Olympic/Figueroa, 9th/Figueroa, 8th/Figueroa, Figueroa/7th, Hope/7th, Olive/7th, 7th/Hill, 5th/Hill, Angel's Flight/Grand Central Market, 2nd/Hill, and 2nd/Grand. A 20 second dwell time was assumed at each stop. Acceleration and deceleration were assumed to be 2.5 MPH per second. Maximum speeds were assumed to be the posted speed limits or the restricted speeds around the 90 degree turns. In addition, an average intersection delay was assumed to be 20 seconds.

Since 2011, many of the downtown streets on the streetcar route have undergone significant transformations. Broadway has been restriped from 2 lanes southbound (SB) and 3 lanes northbound (NB) to 1 lane SB and 2 lanes NB to provide wider sidewalks. Also, 7th Street has been restriped from 2 lanes eastbound (EB) and 2 lanes westbound (WB) to 1 lane EB and 2 lanes WB to provide bike lanes. Bike lanes were added to 1st Street, and bike lanes are proposed for 11th Street by changing the configuration from 2 lanes WB to 1 lane WB, and Figueroa Street will also see a lane reduction to receive bike lanes. These road diets along the streetcar route, coupled with significant new development and re-activation of historic buildings, along with a significant amount of all types of construction, has created traffic congestion along the Project route. AECOM, the City's Project Management Consultant, performed a floating car study that showed an average speed of 4.7 MPH during the afternoon peak period. To maintain a 7-minute headway at 4.7 MPH, it is expected that eight (8) streetcars would need to be placed in service rather than the six (6) previously assumed, increasing the O+M cost, and reducing ridership. To evaluate potential physical and operational treatments that would help improve the streetcar's run time, a Small Starts Speed Improvement analysis was performed. The scope, field observations, methodology and alternatives, assumptions, findings, and conclusions of this analysis are presented in the following sections.

Scope of the Analysis

The scope of the Small Starts Speed Improvement Analysis consisted of field observations, intersection evaluations for the base condition and three improvement scenarios, and streetcar run time estimates for the base condition and four improvement scenarios. It should be noted that one of the four scenarios simply reduced the number of streetcar station stops, while maintaining the improvements proposed to reduce the streetcar's delay and its associated run time.

Field Observations

Field observations were performed over a 2-day period in August 2015 during the PM peak period (from 3:30 to 5:30 PM) to observe traffic operating conditions and identify potential trouble spots that may affect the future streetcar operations. The objective of this site visit was to identify traffic delay locations, determine the possible causes of this delay, and use the information collected to assist in recommending modifications to the roadway system that will assist in alleviating these bottlenecks. This assessment was conducted for the 7th Street streetcar alignment alternative. The focus of the field observations were along Broadway (between 1st and 11th Streets), 11th Street (between Broadway and Figueroa Street), Figueroa Street (between 11th and 7th Streets), 7th Street (between Figueroa and Hill Streets), and Hill Street (between 7th and 1st Streets). In addition, a field inventory was conducted during the site visit to review and verify the intersection lane configuration, the type of traffic control, the signal phasing, and the pedestrian activity. The following traffic conditions were observed at these roadways.

- **Broadway** – heavy northbound and southbound traffic volumes and queue build-up was observed along the roadway segment between 2nd and 8th Streets. For the southbound direction of Broadway, queues and associated delays due to congestion were noticeable at the 3rd, 5th, and 8th Street intersections.
- **11th Street** – westbound traffic along 11th Street flowed freely through the intersections from Broadway to Figueroa Street. There were minor delays for the turning movements waiting for pedestrians to cross the street; however, it did not result in any noticeable queuing conditions.
- **Figueroa Street** – northbound traffic along the segment of Figueroa Street between 11th and 9th Street flowed adequately through the intersections. Significant delays were observed on the northbound approach at 7th Street with queuing developing along the northbound right turn lane and extending to 8th Street. In addition, it was also observed that vehicle queue spillback from 6th Street affected the operations at the intersection of 7th Street and Figueroa Street resulting in delays and queues extending back to the Figueroa Street and 8th Street intersection and beyond. It was also observed that the far side bus stops at Figueroa and 7th Streets resulted in the queuing of buses along the designated Figueroa bus lane between 7th and 8th Streets.
- **7th Street** – eastbound through traffic along the segment between Figueroa and Flower Streets queued due to the existing short right turn lane storage length. Eastbound right turn traffic at 7th Street queued waiting for pedestrians crossing the south leg of Flower Street to clear the crosswalk. During several signal cycles, it was observed that the right turn queue spilled back beyond the right turn lane storage length and blocked the eastbound through movement along 7th Street. Eastbound through traffic along the remaining segments of 7th Street flowed freely through the intersections from Flower Street to Hill Street.
- **Hill Street** – traffic delays and congestion was observed along the northbound segment of Hill Street at the 6th Street and the 5th Street intersections. Northbound right turn traffic at Hill Street queued waiting for pedestrians crossing the east leg of 6th Street to clear the crosswalk. This resulted in the northbound curb lane being blocked thus delaying the northbound through movement along the curb lane of Hill Street, which is the location of the streetcar tracks.

As a result of the field observations, a total of eight intersections were identified as locations of concern that may potentially impact the run time estimates and delay the streetcar's operating speed. The eight intersections of concern are Broadway/3rd Street, Broadway/5th Street, Broadway/8th Street, Figueroa

Street/8th Street, Figueroa Street/7th Street, Flower Street/7th Street, Hill Street/6th Street, and Hill Street/5th Street.

Analysis Methodology and Alternatives

The analysis methodology and alternatives analyzed is divided into two elements; performing the intersection evaluations using the Synchro software to determine the total delay for the streetcar movement and using this information to calculate the streetcar run times.

Intersection Evaluations

The streetcar run time calculation is based on the intersection approach delay for the streetcar movement at each of the 34 signalized intersections along the streetcar alignment. The Synchro V8.0 traffic analysis software was run, during the PM peak hour only, for each of the 34 intersections along the route to determine the total delay for the streetcar movement. The intersection evaluations were performed at 1st /Grand, 1st/Olive, 1st/Hill, 1st/Broadway, 2nd/Broadway, 3rd/Broadway, 4th/Broadway, 5th/Broadway, 6th/Broadway, 7th/Broadway, 8th/Broadway, 9th/Broadway, Olympic/Broadway, 11th/Broadway, 11th/Hill, 11th/Olive, 11th/Grand, 11th/Hope, 11th/Flower, 11th/Figueroa, Olympic/Figueroa, 9th/Figueroa, 8th/Figueroa, 7th/Figueroa, 7th/Flower, 7th/Hope, 7th/Grand, 7th/Olive, 7th/Hill, 6th/Hill, 5th/Hill, 4th/Hill, 3rd/Hill, and 2nd/Hill. The intersection evaluations were performed for the Base Condition and three improvement scenarios.

The Base Condition consisted of running Synchro at the 34 intersections with the streetcar alignment in place using the latest available traffic volumes at each intersection, the latest intersection lane configurations and associated restriping from the development and streetscape projects that have been completed, and the latest traffic signal timing information along Broadway due to the implementation of the streetscape project. All of the latest available information was collected and provided by LADOT.

Scenario 1 consisted of reviewing the results of the field observations and reviewing the streetcar movement delay results from the Base Condition to identify potential physical and operational intersection improvements that would improve the run time estimate. The improvements proposed to improve the streetcar delay are presented in the Assumptions section.

Scenario 2 builds off the improvements proposed in Scenario 1 and would also add a second southbound lane on Broadway from 2nd to 11th Streets. As a result of having two southbound lanes on Broadway, the curb lane includes buses and the streetcar tracks and is designated as a "Transit Only" lane and the second lane will accommodate all other mixed flow vehicles. However, it should be noted that mixed flow vehicles would be permitted to weave across the "Transit Only" lane and the streetcar tracks to access the southbound right turn pocket lanes along Broadway at 2nd, 3rd, 5th, 7th, 8th Streets, and Olympic Boulevard.

Scenario 3 builds off the improvements proposed in Scenario 1 and would designate the single southbound lane on Broadway from 2nd to 11th Streets as a "Transit Only" lane to accommodate buses and the streetcar tracks. All mixed flow vehicles currently traveling in the southbound direction of

Broadway would be diverted to adjacent roadways such as Hill and Spring Streets. Local access to businesses along the southbound direction of Broadway would travel along Hill and Spring Streets and circle back onto the northbound direction of Broadway to access their final destination. Except for transit vehicles, southbound right turn movements at 2nd, 3rd, 5th, 7th, 8th Streets, and Olympic Boulevard would be prohibited. It is assumed that 25 percent of the mixed flow vehicles along southbound Broadway would be local access trips and that 75 percent of the mixed flow vehicles are through trips. The distribution of the southbound through trips between Hill and Spring Streets used the same percentages that were presented in the Broadway Streetscape Plan Traffic Study dated November 2010.

Streetcar Run Time Estimates

To determine estimated streetcar run times, a run time analysis was completed along the corridor in September 2015, replicating the project alignment. The process started with a floating car travel time analysis to determine typical PM peak travel time and delay along the corridor. This analysis was performed to serve as a base to calibrate both an existing Base Condition Synchro network to model traffic signal delays and an existing streetcar run time model to determine streetcar performance if no improvements were made.

The streetcar run time models are based on station to station run times, dwell times and signalized intersection delays for the streetcar movement. The assumptions for each of these parameters are presented in the next section of this document.

Based on the initial Synchro delays, a Base Condition scenario was developed to show projected run times assuming no improvements were made.

Building on the Base Condition, Scenario 1 was developed with minimal improvements including optimization of existing signal timing splits. No Transit Signal Priority (TSP) timings were assumed in this analysis. There were no lane use changes made for Scenario 1. The run times were based on a revised Synchro output which reflected the adjusted signal timings, the addition of a protected right turn phase, where applicable, and the proposed addition of a right turn pocket lane at two intersection locations.

Scenario 2 was developed based on the signal time improvements in Scenario 1 and lane geometry changes along Broadway. Two southbound travel lanes are provided in this scenario from the one southbound lane currently available.

Scenario 3 converts the one southbound lane on Broadway to a transit only lane, including the streetcar. Scenario 3 also assumed the signal timing improvements made for Scenario 1.

Scenario 4 incorporates the incremental signal timing improvements included in Scenario 1, but consolidates the number of streetcar station stops from 25 to 16 and spaces them about every 1/4 mile from every 1/8 mile. The stations included in Scenario 4 are: 2nd/Grand, 2nd/Broadway, 4th/Broadway, 6th/Broadway, 8th/Broadway, Olympic/Broadway, 11th/Grand, 11th/Figueroa, 9th/Figueroa, 7th/Figueroa, 7th/Grand, 7th/Hill, 5th/Hill, Angel's Flight/Grand Central Market, 2nd/Hill, and 2nd/Grand.

Results of the run time analyses are presented later on in the technical memorandum.

Assumptions

The following assumptions were made for the Small Starts Speed Improvement Analysis for each of the intersection evaluations and the run time estimates.

Intersection Evaluations

- Existing (2015) intersection lane configurations were collected and verified by field observations;
- The analysis was based on existing 2014/2015 traffic counts provided by LADOT;
- Available traffic counts that are older than 2014/2015 were used and grown by an annual growth rate of 0.5% per year to reflect existing conditions (this ambient growth rate was used in the EIR traffic study and approved by LADOT);
- Existing signal timing was used. LADOT provided the latest signal timing changes along Broadway that were implemented due to the Streetscape Demonstration Project;
- Existing signal cycle lengths were maintained. The general PM peak hour cycle length is 90 seconds for the analyzed intersections. All current signal off-set parameters remained the same in the analysis;
- On one lane roadways, the bus blockage factor in the Synchro software was utilized to account for potential delays due to near side stops and the anticipated 20-second dwell time for passengers to board and alight;
- Extended yellow clearance times used in the EIR traffic study to reflect the potential for a streetcar to arrive at the intersection near the end of the green time and needing an extra clearance interval to safely clear the intersection were maintained;
- The traffic analysis was based on the streetcar characteristics that were presented and approved in the EIR traffic study. This included a 7-minute headway streetcar operation during the peak hours (9 streetcars per hour);
- Proposed improvements to reduce the streetcar delay consisted of:
  - Redistributing the green time within the existing signal cycle length to provide more green to the streetcar movement/direction. The amount of green time ranged from 5 to 15 seconds and depended on the needs at each intersection;
  - Adding a right turn only pocket lane. This was proposed at Broadway/11th Street and at Hill/6th Street;
  - Providing a protected right turn arrow to clear the right turn queue before or after the crossing of pedestrians. This was proposed at Broadway/3rd Street, Broadway/5th Street, Broadway/8th Street, and Figueroa/7th Street;
  - Extending the existing eastbound right turn lane storage length at Flower/7th Street to accommodate 6 to 7 turning vehicles in order to minimize queue spillover onto the eastbound 7th Street through movement.

The assumed physical and operational intersection improvements are intended to reduce the streetcar delay. Ongoing coordination between City of Los Angeles and Metro will be required for implementing these improvements

Streetcar Run Time Estimates

The estimated vehicle run time models are based on typical streetcar acceleration/deceleration rates of 2.5 mph per second and average dwell times of 20 seconds at each stop. The signal delay times are based on the Synchro output of total delay for the streetcar movement at each of the signalized intersections along the streetcar alignment within the study area. The total delay at signalized exclusive pedestrian crossings was assumed to be 10 seconds per signal.

The run time analysis does not include any layover times, and a total cycle time was not analyzed for the purpose of this estimate. It is assumed that the vehicle layover will occur at the 2^{nd}/Grand station.

Station locations, distances and curve data at intersections were based on the previous concept plans that are being used as the basis of the Environmental Documents. The maximum allowable streetcar speed was assumed to be the same as the posted speed limits.

Findings

The results and findings of the intersection evaluations and streetcar run time estimates for the Base Condition and various improvement scenarios are presented in the following sections.

Intersection Evaluations

The total delay for the streetcar movement was reported at each of the 34 intersections for each of the analysis scenarios. The attached summary table presents the PM peak hour delay for each scenario that was evaluated along with the improvements proposed. As shown from the results, the delays in Scenario 1 improve from the Base Condition due to the improvements proposed at thirteen intersection locations. In addition, improvements are proposed at three intersection locations based on the field observations. Scenario 2 continues to improve the delay, from Scenario 1, at eight intersection locations along Broadway. Scenario 3 continues to improve the delay, from Scenario 2, at eight intersection locations along Broadway. The delay numbers that improve from the previous scenario are shown in bold in the summary table. In addition, it should be noted that Scenario 3, which consists of the "Transit Only" lane along southbound Broadway, results in six (6) intersections being significantly impacted when the overall intersection delay is compared to that of the Base Condition. The six significantly impacted intersection locations are at 1^{st}/Hill, 3^{rd}/Hill, 7^{th}/Hill, Olympic/Hill, Olympic/Broadway, and

PM Peak Hour Delay for the Movements Along the Streetcar Alignment – Summary Table

PM Peak Hour Delay per Vehicle (Seconds per Vehicle)						
Intersection	**Movement**	**Base Condition**	**Scenario 1**	**Scenario 2**	**Scenario 3**	**Improvements Proposed For Scenarios 1, 2, and 3**
Grand Ave / 1st St	NB Right	11	11	11	11	(Note that EIR assumes new protected streetcar phase for NB right turn from median)
Grand Ave / 1st St	WB Left	74	**49**	49	49	Redistribute the green time within the existing cycle length
Olive St / 1st St	EB Thru	32	32	32	32	
Olive St / 1st St	WB Thru	23	23	23	23

Broadway / 4th St	SB Thru	29	30	**28**	36	
Hill St / 5th St	NB Thru	29	**15**	15	15	Redistribute the green time within the existing cycle length
Broadway / 5th St	SB Thru	29	30	**28**	35	Provide a protected SB right turn arrow (except for Scenario 3)
Hill St / 6th St	NB Thru	13	**6**	6	7	Add a NB right turn only lane and redistribute the green time within the existing cycle length
Broadway / 6th St	SB Thru	25	25	**23**	**21**	
Figueroa St / 7th St	NB Right	22	**5**	5	5	Provide a protected NB right turn arrow
Flower St / 7th St	EB Thru	15	15	15	15	Extend the existing EB right turn lane storage length
Hope St / 7th St	EB Thru	10	10	10	10	
Grand Ave / 7th St	EB Thru	30	30	30	30	
Olive St / 7th St	EB Thru	11	11	11	11	
Hill St / 7th St	EB Left	31	31	31	31	(Note that EIR assumes new protected EB left turn phase)
Broadway / 7th St	SB Thru	18	18	**16**	**2**	
Figueroa St / 8th St	NB Thru	139	**36**	36	36	Redistribute the green time within the existing cycle length
Broadway / 8th St	SB Thru	104	**29**	**24**	**8**	Provide a protected SB right turn arrow and redistribute the green time within the existing cycle length
Figueroa St / 9th St	NB Thru	35	**28**	28	28	Redistribute the green time within the existing cycle length
Broadway / 9th St	SB Thru	17	25	**20**	**17**	
Figueroa St / Olympic Blvd	NB Thru	18	16	16	16	
Broadway / Olympic Blvd	SB Thru	35	**26**	**22**	**13**	Redistribute the green time within the existing cycle length
Figueroa St / 11th St	WB Right	25	25	25	25	
Flower St / 11th St	WB Thru	21	21	21	20	
Hope St / 11th St	WB Thru	50	**38**	38	38	Redistribute the green time within the existing cycle length
Grand Ave / 11th St	WB Thru	19	19	19	19	
Olive St / 11th St	WB Thru	25	22	22	22	
Hill St / 11th St	WB Thru	43	**25**	25	27	Redistribute the green time within the existing cycle length
Broadway / 11th St	SB Right	87	**9**	9	**2**	Add a SB right turn only lane

Scenario 1 = The Base Condition with the Proposed Intersection/Signal Timing Improvements

Scenario 2 = The Proposed Intersection/Signal Timing Improvements from Scenario 1 plus Two SB Lanes (1 MF & 1 Transit Only) on Broadway from 2nd to 11th Streets

Scenario 3 = The Proposed Intersection/Signal Timing Improvements from Scenario 1 (where applicable) plus One SB Transit Only Lane on Broadway from 2nd to 11th Streets

Olympic/Main. These locations show significant impacts from the Base Condition due to the fact that mixed flow vehicles were diverted to the adjacent roadways, such as Hill Street and Spring/Main Streets. The Synchro delay worksheets, at each intersection location, for the Base Condition and all three scenarios are presented in Attachment 1. It should be noted that Scenarios 2 and 3, which include a "Transit Only" lane along the southbound direction of Broadway, do not show a greater reduction in delay than what would be anticipated over Scenario 1 because the overall intersection cycle length and green times are allocated so that all traffic volumes and movements, as well as pedestrian movements, are accommodated adequately to clear the intersection and minimize queuing and prevent potential spillback to adjacent upstream intersections.

Streetcar Run Time Estimates

The results of the streetcar run time analyses for all scenarios, including the Base Condition are shown in the table below. The detailed run time worksheets are presented in Attachment 2.

Streetcar Run Time Analysis Results

Scenario	Run Time (hr:min:sec)	Delay Time (hr:min:sec)	Dwell Time (hr:min:sec)	Total Time (hr:min:sec)	Average Speed (mph)
Base Case Synchro Output	00:13:11	00:24:59	00:07:40	00:45:50	5.0
Scenario 1 Synchro Output - Base with Improvements	00:13:11	00:17:42	00:07:40	00:38:33	5.9
Scenario 2 Synchro Output - Two SB Broadway Lanes	00:13:11	00:17:08	00:07:40	00:37:59	6.0
Scenario 3 Synchro Output - Broadway Transit Only Lane	00:13:11	00:16:12	00:07:40	00:37:03	6.1
Scenario 4 Synchro Output - Base Case with Improvements and 16 Stops	00:11:36	00:17:42	00:04:40	00:33:58	6.7

As shown in the table, Scenario 4, with the 16 station stops, provides the fastest streetcar run time at just under 34 minutes. With the full 25 station stops, Scenario 3 provides the fastest run times at just over 37 minutes.

Conclusions

Redistributing 5 to 15 seconds of green time at 11 intersections, providing a protected right turn phase at 4 intersections, extending the right turn lane at one location, and providing new right turn lanes at two locations (Scenario 1), saves seven minutes of run time, getting us within 3.5 minutes of the 35 minute run time goal.

Adding a second lane southbound on Broadway with one of the two lanes being transit-only (Scenario 2) saves 34 seconds of run time compared to Scenario 1.

Converting the one southbound lane on Broadway to transit-only (Scenario 3) saves 90 seconds of run time compared to Scenario 1, but causes significant traffic impacts at six intersection locations.

Reducing the number of streetcar station stops from 25 to 16 by increasing the spacing from about 1/8 mile to 1/4 mile (Scenario 4), saves 4.5 minutes in run time compared to Scenario 1. Combined with the proposed Scenario 1 modifications, this would achieve the goal of a run time of less than 35 minutes. A STOPS ridership estimate was performed by Metro with the reduced number of streetcar station stops. The result was a reduction of 300 boardings per day, from 5,700 riders to 5,400 riders. The STOPS model results are presented in Attachment 3.

RE: Los Angeles Streetcar Maintenance and Storage Facility Site Selection

1. Introduction

The Restoration of Historic Streetcar Service in Downtown Los Angeles Project (Project) consists of the construction and operation of streetcar service in downtown Los Angeles, California, along a 3.8-mile one-way loop. The Project alignment would begin at Hill and 1st Streets, run east along 1st Street, south along Broadway, west along 11th Street, north along Figueroa Street, east along 7th Street or 9th Street, and north along Hill Street, back to its beginning at 1st Street. Potential inclusion of a Grand Avenue Extension would also provide a two-way alignment spur west along 1st Street, beginning at Hill Street, and continuing south along Grand Avenue to a stop north of 2nd Street.

The purpose of the maintenance and storage facility (MSF) is to provide a location for secure storage of the vehicles when they are not in operation and a location with equipment and facilities to conduct regular maintenance of the vehicles to keep them clean and in good operating condition. This memo identifies four potential streetcar MSF sites that will be cleared environmentally; one of the four sites will eventually be constructed. Once a recommended site has been selected and the environmental process has been completed, real estate acquisition, final design, and construction can begin.

2. Preliminary MSF Site Selection

A search for potential MSF sites was initiated with a geographic search, which provided a list of more than 7,000 parcels within the boundaries formed by U.S. 101, Interstate 110, Interstate 10, and Los Angeles Street. These boundaries limited the search to parcels in proximity to the streetcar alignment. Areas north of U.S. 101 were not considered because that vicinity would require crossing the freeway with a non-revenue lead track, at an unnecessary and undesirable cost.

Based on preliminary analysis for planning purposes, the MSF site location should satisfy the following selection criteria:

- Be located within ½ mile of the streetcar mainline;
- Support a minimum facility size for a maintenance building, approximately 60 feet wide by 185 feet long, and streetcar storage yard, approximately 65 feet wide by 185 feet long, with additional areas available for parts storage and employee parking;
- Minimize the number of exterior access points where streetcar vehicles move into or out of public roadways

during operations within the site;

- Place special track work within the public right-of-way where possible to minimize the site area but, at the same time, avoid yard movements that encroach into the public right-of-way; and
- Avoid reverse movements for daily operations as much as possible by:
  - Maintaining a “pull-through” inspection pit for daily inspections of streetcar underbodies, and
  - Following a preferred flow of streetcars at the end of the service day, which would be (a) through the car wash and over a pit for daily inspection, then (b) into either the shop or the streetcar storage area.

The MSF site would need to also satisfy the following space and site requirements:

- Size the facility to accommodate 12 streetcars;
- Assume streetcar dimensions of approximately 82 feet by 8 feet. Allow for access around the ends of streetcars and 9 feet wide to allow some buffer between streetcars and adjacent obstructions;
- Assume a minimum of three interior bays (which can also be utilized for storage; the other nine vehicles can be stored on outdoor tracks);
- Include a vehicle wash bay, approximately 100 feet long (which can also be utilized for storage), or consider hand washing as a space-saving alternative;
- Track Center Dimensions: Minimum track centers of 15 feet, allowing 7.5 feet of clearance on either side of vehicle for circulation;
- Minimum radius curves of 66 feet for track alignments into and within the yard;
- Maintenance building footprint of approximately 12,000 square feet, including a shop, office, and storage space, and a minimum ceiling height of 22 feet to account for aerial walkways, which would be used to service roof-mounted equipment:
  - This assumes a staff of 19, including supervisor and maintenance staff. It does not include the staff that will not need office space, such as operators or fare inspectors;
  - The office building is assumed to be approximately 4,000 square feet. This is already included in the maintenance building footprint area, above;
- Automobile parking is not included in the minimum site dimensions but would be useful to provide if space is available. If so, it is recommended that 20 spaces be provided for employee and visitor parking:
  - Creative parking options could be utilized, such as shared parking at another site, street parking, alternative modes of transportation for employees, etc.;
  - Parking could be fitted into underused areas on-site once the trackwork and building footprint are designed; and
- Access and an area for delivery trucks to pull into the site and offload will need to be included as the designs are developed.

- A traction power substation (TPSS) is not to be explicitly included in the site area but would most likely be able to fit within the MSF building footprint and/or site area provided:
    - If outside the MSF, a TPSS unit is assumed to be approximately 11 feet by 17 feet, with access drive on one long side; and
    - If housed within the MSF, a TPSS unit is assumed to be approximately 5 feet by 15 feet. It could be co-located in the electric room.

The above criteria would require a site size of approximately one or two acres. The size range varies because it depends on the shape of the site, exactly which streetcar operations and maintenance functions are housed at this location, and whether or not the site will include employee parking. These size requirements were used broadly to eliminate potential sites with areas that are too small to be considered.

3. Preliminary MSF Site Selection

Other considerations for determining MSF sites included:

- Estimated Comparable Costs
    - Property Cost
    - Yard Lead Track Cost
- Downtown Design Guidelines
- Operability of Site Layout
- Proximity to Mainline: Yard Lead Track
- Site Slope/Need for Retaining Walls
- Need for Demolition Work
- Extent of Yard Track and Special Track work
- Parcel Ownership

Estimated Comparable Costs

Estimated comparable costs include estimates of costs and quantities that can vary by site. They do not include all costs associated with construction of an MSF site and are therefore used for comparative purposes only.

For those sites that met the minimum area criteria, an estimated property cost and yard lead track cost were applied, based on the absolute minimum site area and the distance of the site from the mainline.

Property Cost

The price to acquire property will most likely be the largest cost in the development of an MSF site. Eight large comparable property sites near the study area that were sold or are for sale, with no building improvements, were used to identify various cost levels for the site options at the time of the initial assessment in late 2011. These cost levels were $150/SF, $200/SF, and $250/SF, with $250/SF being premium properties near areas such as LA Live and Staples Center and $150/SF being lower-end properties in former redevelopment areas.

The estimated property cost for each site was based on one of the assumed per-square-foot cost levels and the absolute minimum site area defined above. (Note that this assumes partial parcels can be acquired to minimize the area purchased. The actual purchase area will vary with each site, as will the actual per-square-foot costs; therefore, the estimated land value should not be considered final.)

Yard Lead Track Cost

Non-revenue yard lead track should be minimized as much as possible. A long non-revenue yard lead track is often single or double tracked, operating within street or alley rights-of-way. The yard lead track does not carry passengers or generate revenue, yet it requires the same type of track and overhead catenary system (OCS) construction as the mainline track. Therefore, an estimate of yard lead track, based on the distance from the site to the mainline, was determined and applied to a per-track-foot cost for yard lead track.

The costs associated with yard lead track include guideway preparation, track, utility relocations, and OCS, with a 30% contingency, 5% escalation per year to mid-point of construction, 30% professional services, and another 10% unallocated contingency. This results in a per-track-foot cost of approximately $1,900 per track foot. (Note that this assumes single track for the yard lead track. Depending on how a site is developed and the streets leading to it, it may be necessary to separate inbound and outbound vehicles traveling to and from the maintenance facility, which would require double track. Therefore, the estimated yard lead track cost should not be considered final).

Downtown Design Guidelines

In addition to the characteristics above, the following Downtown Design Guidelines and Street Guidelines were also examined for screening criteria:

- Preserve existing buildings as much as possible, especially historic buildings;
- Provide 18- to 24-inch access zone next to curb, plus a continuous landscaped parkway (varying between 4 feet and 7 feet, depending on sidewalk width), plus a 6-foot continuous travel path;
- Avoid closing alleys where possible; and
- Line the edge of the property with an attractive façade—no chain link, barbed wire, or roll-up doors.

Operability of Site Layout

An ideal site layout was created that maximizes operability while minimizing the site area required. All site layouts were compared and ranked against this ideal layout. The ideal layout would be an L- shape with one point of entrance/exit. Upon entering the yard, the streetcars would first run through a car wash (40 feet by 100 feet) and then proceed to either the maintenance shop or the storage yard without requiring reversing movements. The vehicles should also be able to proceed from storage to the mainline without reversing movements. All reversing movements between the shop and storage area are to be kept within the site to avoid off-site traffic impacts.

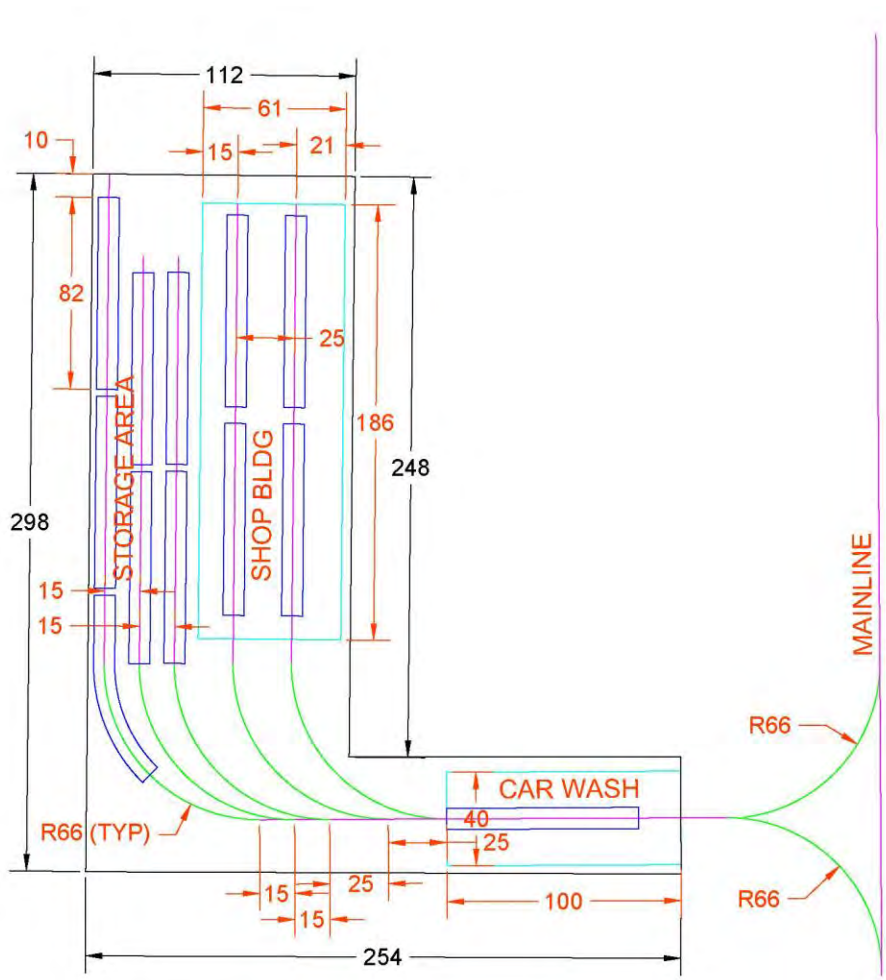

Figure 1: Potential MSF layout

The shop dimensions would be approximately 61 feet by 185 feet to hold four vehicles, though, for tight sites, two workspaces, with one long-term space, may be adequate for a fleet size of 12 vehicles. The shop tracks would be separated by a minimum of 25 feet. One side of the shop would require 21 feet from track to shop wall (15 feet for a work area and a 6-foot access aisle). The other side would provide a minimum of 15 feet from track to shop wall. The storage area and car wash would house the remaining vehicles, for a total of 12 vehicles stored on-site.

Proximity to Mainline: Yard Lead Track

Sites that would be located more than one block away from the mainline were removed from consideration to avoid a long non-revenue yard lead track. Each site's yard lead track was refined, based on its unique site layout. The updated yard lead track cost was incorporated into the site's estimated comparable cost.

Site Slope/Retaining Wall

Because of the large amount of special track work within the MSF yard, finished sites must have a zero percent slope. For sloped sites that would require grading and retaining walls to achieve a zero percent slope, a retaining wall allowance was added to the site's estimated comparable cost.

Demolition Work

Sites that include existing buildings, utilities, and/or paving, that would need to be demolished were assigned a demolition allowance to account for the added costs of demolition work. This cost was added to the site's estimated comparable cost.

Yard Track and Special Trackwork

Because of dimensional constraints, some sites would require significantly more yard track or special track work. This would add to the site's development cost. Therefore, the amount of yard track and special track work was estimated, based on site layouts, and added to the site's estimated comparable cost.

Estimated Land Value: Property Cost

The estimated land values were based on one of the assumed per-square-foot cost levels, described above in the discussion of initial criteria, estimated comparable costs, and property cost, and the specific site area required based on each site's unique layout. This updated land value cost was incorporated into the site's estimated comparable cost. (Note that this assumes that partial parcels could be acquired to minimize the area purchased. The actual purchase area will vary with each site option, as will the actual per-square-foot costs; therefore, the estimated land value should not be considered final) .

Parcel Ownership

No publicly owned sites were identified. Private property owners were contacted to determine their potential willingness to sell all or a portion of their property for an MSF site. All the property owners expressed potential willingness to sell for purposes of future use as an MSF site.

4. Recommended Potential MSF Sites

Based on the above criteria, four sites were chosen to be evaluated in the environmental analysis. The sites are shown in Figure 2. It was determined that all the sites have agreeable owners, and the property values were fairly comparable.

Site 1: The northeast corner of 12th Street and Grand Avenue is the location of one potential MSF site. Three parcels located there would total 92,815 square feet. There are no existing buildings on the potential site that would require demolition. No retaining walls would be needed at this location. A total of 165 feet of track lead and 1,215 track feet of yard track are estimated to serve a 12,378-square-foot MSF facility. A hand wash area for vehicles would be required at this location. Also, the closure of an alley may be required. A 100-foot car wash would not fit prior to entering the shop area, and a 40-foot width would not fit in an alley storage area. The site is less than one block from the mainline and would allow for an easy exit from the storage area to the mainline.

Site 2: Three parcels on the southeast corner of 11th and Olive Streets, totaling 47,915 square feet, could serve as an MSF site. The site is 152 feet long along 11th Street, and 304 feet long along Olive Street. Because the site is smaller than optimum (the depth of the site is 304 feet versus the desired 320 feet), the site would require a turntable to achieve a compact layout that would fit within the site. One potential turntable supplier would be Macton Corporation (dlouder@macton.com). A turntable would cost approximately $800,000.

Site 3: Seven parcels on the northwest corner of 5th and Hill Streets make up 98,690 square feet, which could be the site of an MSF. The parcels are zoned as residential, though they are existing parking lots. A total of 500 track feet of track lead and 1,275 track feet of yard track could be accommodated, and a 26,010-square-foot facility could be provided.

Site 4: Properties located midblock between 2nd and 3rd Street and between Hill Street and Broadway are also a potential MSF site. The four parcels total 57,719 square feet. A facility of approximately 25,115 square feet would accommodate approximately 104 track feet of track lead and 1,405 track feet of yard track. No existing buildings on-site would require demolition. A retaining wall would most likely be required at this site. It was determined that a leaking underground storage tank was found on the southeast corner of the lots. This would need to be investigated in final design. This location could provide an ideal layout for an MSF.

Figure 2: Potential MSF Sites

5. Conclusion

This analysis looked at possible sites from a planning perspective. All sites listed are suitable for streetcar maintenance and storage based on current information available. However, the final design team will need to determine the final locations and layout of the MSF. Further analysis will be necessary in order to finalize the specific MSF sites for the project.

Appendix L
Small Starts Speed Improvement Analysis, Technical Memorandum

Restoration of Historic Streetcar Service in Downtown Los Angeles

Small Starts Speed Improvement Analysis
Technical Memorandum

Executive Summary

A Small Starts Speed Improvement Analysis has been performed to evaluate potential physical and operational treatments that would improve the run time of the Downtown Los Angeles Streetcar Project. The table below summarizes the results for the afternoon peak hour (worst case condition).

Streetcar Run Time Analysis Results

	Existing	Baseline	Scenario 1	Scenario 2	Scenario 3	Scenario 4
Description	Without Improvement (AECOM Estimate)	EIR Assumed 3 Protected Turn Phases	Additional Improvements at 16 Locations	Scenario 1 + Transit-Only Lane (2 SB Lanes)	Scenario 1 + Transit-Only Lane (1 SB Lane)	Scenario 1 + Stop Reduction (25 to 16)
Travel Time	49.5 min	45.8 min	38.5 min	38 min	37 min	34 min
Speed	4.7 mph	5.0 mph	5.9 mph	6.0 mph	6.1 mph	6.7 mph
Approx. Ridership (7th with Grand Ave)	4,400	4,800	5,700	5,700	5,700	5,400

The existing run-time estimate performed by AECOM added two minutes of delay adjustment and did not have the benefit of protected left turn signal phases at 7th and Hill and 1st and Hill. HDR's run-time estimate spreadsheet was modified with intersection delays calculated by Syncho.

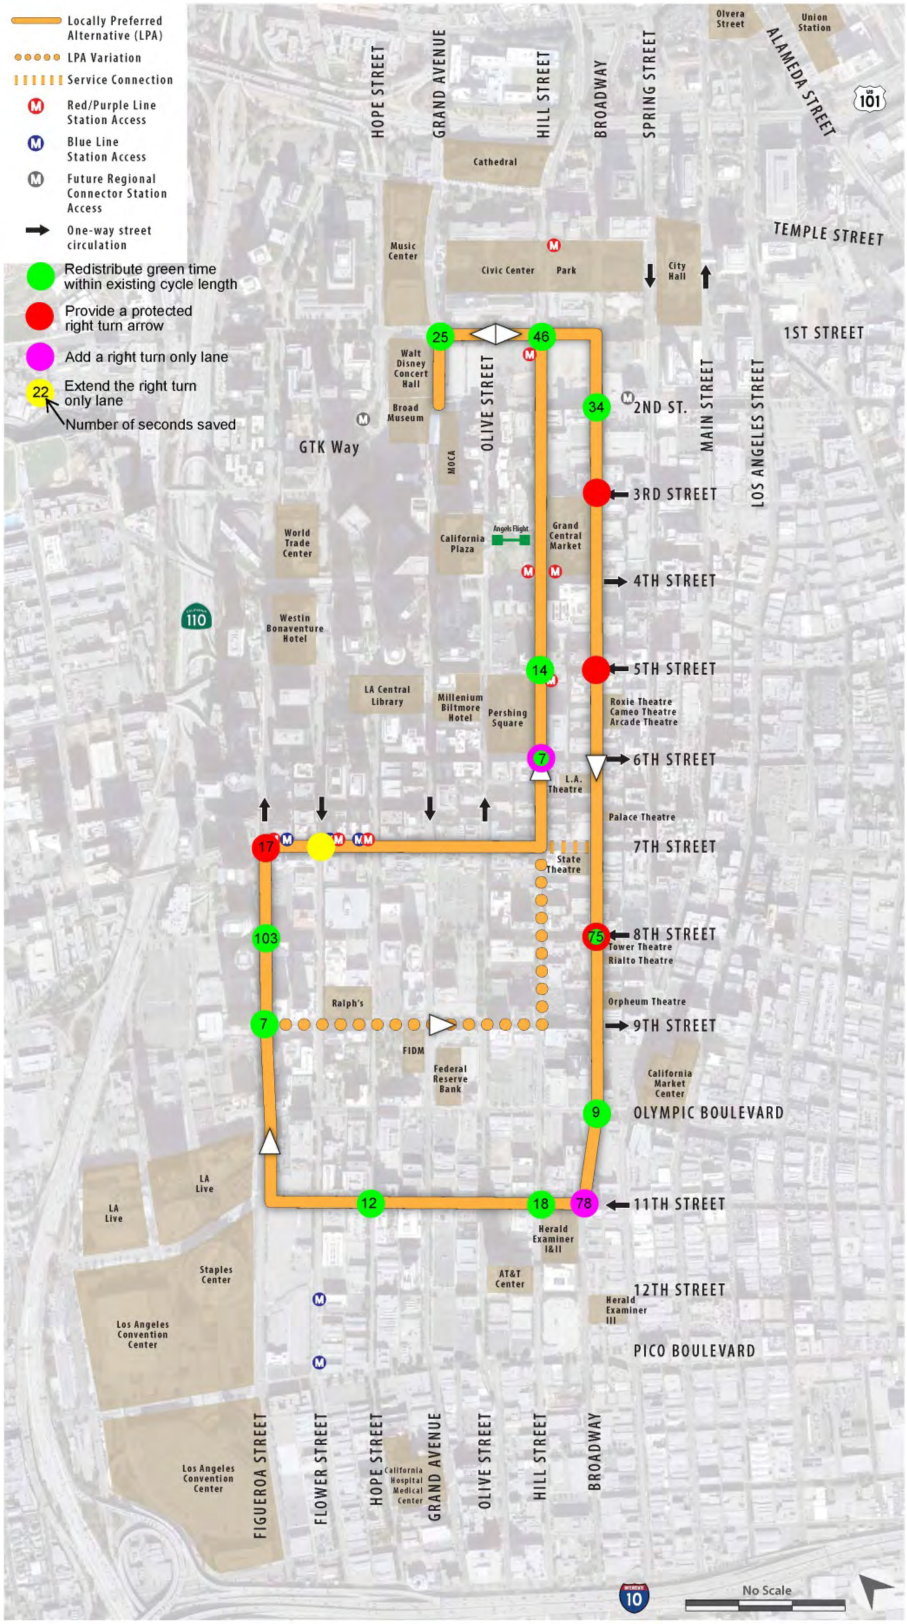
Scenario 1, redistributing 5 to 15 seconds of green time at 11 intersections, providing a protected right turn phase at 4 intersections, extending the right turn lane at one location, and providing new right turn lanes at two locations, saved seven minutes of run time, and got within 3.5 minutes of the 35 minute run time goal. The map on the next page shows where the Scenario 1 improvements are proposed and the resulting run time savings.

Scenario 2, adding a second lane southbound on Broadway with one of the two lanes being transit-only, saves 34 seconds of run time compared to Scenario 1.

Scenario 3, converting the one southbound lane on Broadway to transit-only, saves 90 seconds of run time compared to Scenario 1, but causes significant traffic impacts at six intersection locations.

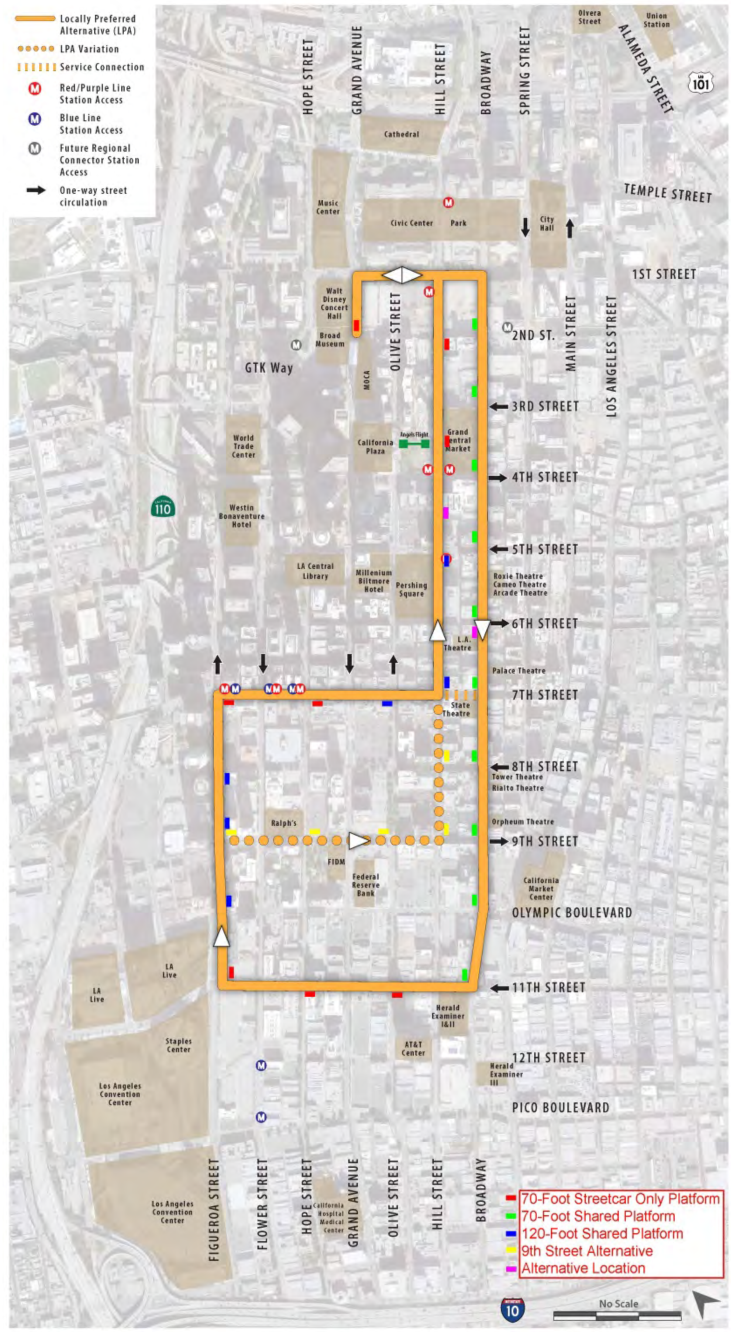
Scenario 4, reducing the number of streetcar station stops from 25 to 16, saves 4.5 minutes in run time compared to Scenario 1. Combined with the proposed Scenario 1 modifications, Scenario 4 achieves the goal of a run time of less than 35 minutes. However, a ridership estimate was performed by Metro with the reduced number of streetcar station stops, and the result was a reduction of 300 boardings per day, from 5,700 riders to 5,400 riders.

Scenario 1 Improvements



Introduction

The Downtown Los Angeles Streetcar (Project) is a 3.8-mile loop that starts in an exclusive median on Grand Avenue just north of 2nd Street. It turns right on 1st Street, turns right on Broadway, turns right on 11th Street, turns right on Figueroa Street, turns right on 7th Street, turns left on Hill Street, turns left on 1st Street, and turns left on Grand Avenue back to the starting point. There is variation to the locally preferred alternative (LPA) that uses 9th Street that will also need to be considered in the environmental document.



The Project is seeking FTA funding for the construction and project development costs through the Federal Transit Administration (FTA) Capital Investment Grant Program. The FTA will evaluate the project against six Project Justification Factors (Mobility Improvements, Environmental Benefits, Congestion Relief, Cost-Effectiveness, Economic Development, and Land Use), and overall the Project must receive at least a medium rating in order to receive funding. The critical elements of this evaluation are ridership, capital cost, and operations and maintenance (O+M) cost.

Ridership has more impact on the overall rating than any other factor because it affects three of the six justification factors. FTA requires all of its projects to estimate ridership using a software program that they have developed called STOPS (Simplified Trips on Project Software). When the project is submitted to FTA for a rating, it will need to have a ridership estimate, a detailed operating plan, and proposed physical improvements that are all consistent with one another. In addition, the FTA will be the lead agency for NEPA clearance, and the environmental document will have to be consistent with each of these other elements. The FTA will need evidence and documentation to back up the estimated run time for the transit service, because this affects the ridership and determines the number of streetcar vehicles that will need to operate to achieve the planned service headway. The FTA will be checking the capital cost estimate to be sure that the correct number of vehicles is included in the project capital cost estimate, that the O+M estimate reflects all of these vehicles in service, and that the MSF facility is sized appropriately to accommodate the vehicle fleet. The run time is a critical factor for the project.

As part of the Alternatives Analysis, in 2011, the project team prepared operating plans and O+M estimates for the seven alignments being evaluated as part of the final screening. For the two alternatives that were selected as the LPA, the streetcar run time was estimated to be 35.5 minutes, requiring 6 vehicles to meet the peak 7-minute headway plus one spare. This equates to an average speed of 6.5 miles per hour (MPH). The estimate was based on 25 stops at 2^{nd}/Grand, 2^{nd}/Broadway, 3^{rd}/Broadway, 4^{th}/Broadway, 5^{th}/Broadway, 6^{th}/Broadway, 7^{th}/Broadway, 8^{th}/Broadway, 9^{th}/Broadway, Olympic/Broadway, 11^{th}/Broadway, Olive/11^{th}, Hope/11^{th}, 11^{th}/Figueroa, Olympic/Figueroa, 9^{th}/Figueroa, 8^{th}/Figueroa, Figueroa/7^{th}, Hope/7^{th}, Olive/7^{th}, 7^{th}/Hill, 5^{th}/Hill, Angel's Flight/Grand Central Market, 2^{nd}/Hill, and 2^{nd}/Grand. A 20 second dwell time was assumed at each stop. Acceleration and deceleration were assumed to be 2.5 MPH per second. Maximum speeds were assumed to be the posted speed limits or the restricted speeds around the 90 degree turns. In addition, an average intersection delay was assumed to be 20 seconds.

Since 2011, many of the downtown streets on the streetcar route have undergone significant transformations. Broadway has been restriped from 2 lanes southbound (SB) and 3 lanes northbound (NB) to 1 lane SB and 2 lanes NB to provide wider sidewalks. Also, 7^{th} Street has been restriped from 2 lanes eastbound (EB) and 2 lanes westbound (WB) to 1 lane EB and 2 lanes WB to provide bike lanes. Bike lanes were added to 1^{st} Street, and bike lanes are proposed for 11^{th} Street by changing the configuration from 2 lanes WB to 1 lane WB, and Figueroa Street will also see a lane reduction to receive bike lanes. These road diets along the streetcar route, coupled with significant new development and re-activation of historic buildings, along with a significant amount of all types of construction, has created traffic congestion along the Project route. AECOM, the City's Project Management Consultant, performed a floating car study that showed an average speed of 4.7 MPH during the afternoon peak period. To maintain a 7-minute headway at 4.7 MPH, it is expected that eight (8) streetcars would need to be placed in service rather than the six (6) previously assumed, increasing the O+M cost, and reducing ridership. To evaluate potential physical and operational treatments that would help improve the streetcar's run time, a Small Starts Speed Improvement analysis was performed. The scope, field observations, methodology and alternatives, assumptions, findings, and conclusions of this analysis are presented in the following sections.

Scope of the Analysis

The scope of the Small Starts Speed Improvement Analysis consisted of field observations, intersection evaluations for the base condition and three improvement scenarios, and streetcar run time estimates for the base condition and four improvement scenarios. It should be noted that one of the four scenarios simply reduced the number of streetcar station stops, while maintaining the improvements proposed to reduce the streetcar's delay and its associated run time.

Field Observations

Field observations were performed over a 2-day period in August 2015 during the PM peak period (from 3:30 to 5:30 PM) to observe traffic operating conditions and identify potential trouble spots that may affect the future streetcar operations. The objective of this site visit was to identify traffic delay locations, determine the possible causes of this delay, and use the information collected to assist in recommending modifications to the roadway system that will assist in alleviating these bottlenecks. This assessment was conducted for the 7th Street streetcar alignment alternative. The focus of the field observations were along Broadway (between 1st and 11th Streets), 11th Street (between Broadway and Figueroa Street), Figueroa Street (between 11th and 7th Streets), 7th Street (between Figueroa and Hill Streets), and Hill Street (between 7th and 1st Streets). In addition, a field inventory was conducted during the site visit to review and verify the intersection lane configuration, the type of traffic control, the signal phasing, and the pedestrian activity. The following traffic conditions were observed at these roadways.

- **Broadway** – heavy northbound and southbound traffic volumes and queue build-up was observed along the roadway segment between 2nd and 8th Streets. For the southbound direction of Broadway, queues and associated delays due to congestion were noticeable at the 3rd, 5th, and 8th Street intersections.
- **11th Street** – westbound traffic along 11th Street flowed freely through the intersections from Broadway to Figueroa Street. There were minor delays for the turning movements waiting for pedestrians to cross the street; however, it did not result in any noticeable queuing conditions.
- **Figueroa Street** – northbound traffic along the segment of Figueroa Street between 11th and 9th Street flowed adequately through the intersections. Significant delays were observed on the northbound approach at 7th Street with queuing developing along the northbound right turn lane and extending to 8th Street. In addition, it was also observed that vehicle queue spillback from 6th Street affected the operations at the intersection of 7th Street and Figueroa Street resulting in delays and queues extending back to the Figueroa Street and 8th Street intersection and beyond. It was also observed that the far side bus stops at Figueroa and 7th Streets resulted in the queuing of buses along the designated Figueroa bus lane between 7th and 8th Streets.
- **7th Street** – eastbound through traffic along the segment between Figueroa and Flower Streets queued due to the existing short right turn lane storage length. Eastbound right turn traffic at 7th Street queued waiting for pedestrians crossing the south leg of Flower Street to clear the crosswalk. During several signal cycles, it was observed that the right turn queue spilled back beyond the right turn lane storage length and blocked the eastbound through movement along 7th Street. Eastbound through traffic along the remaining segments of 7th Street flowed freely through the intersections from Flower Street to Hill Street.
- **Hill Street** – traffic delays and congestion was observed along the northbound segment of Hill Street at the 6th Street and the 5th Street intersections. Northbound right turn traffic at Hill Street queued waiting for pedestrians crossing the east leg of 6th Street to clear the crosswalk. This resulted in the northbound curb lane being blocked thus delaying the northbound through movement along the curb lane of Hill Street, which is the location of the streetcar tracks.

As a result of the field observations, a total of eight intersections were identified as locations of concern that may potentially impact the run time estimates and delay the streetcar's operating speed. The eight intersections of concern are Broadway/3rd Street, Broadway/5th Street, Broadway/8th Street, Figueroa

Street/8th Street, Figueroa Street/7th Street, Flower Street/7th Street, Hill Street/6th Street, and Hill Street/5th Street.

Analysis Methodology and Alternatives

The analysis methodology and alternatives analyzed is divided into two elements; performing the intersection evaluations using the Synchro software to determine the total delay for the streetcar movement and using this information to calculate the streetcar run times.

Intersection Evaluations

The streetcar run time calculation is based on the intersection approach delay for the streetcar movement at each of the 34 signalized intersections along the streetcar alignment. The Synchro V8.0 traffic analysis software was run, during the PM peak hour only, for each of the 34 intersections along the route to determine the total delay for the streetcar movement. The intersection evaluations were performed at 1st /Grand, 1st/Olive, 1st/Hill, 1st/Broadway, 2nd/Broadway, 3rd/Broadway, 4th/Broadway, 5th/Broadway, 6th/Broadway, 7th/Broadway, 8th/Broadway, 9th/Broadway, Olympic/Broadway, 11th/Broadway, 11th/Hill, 11th/Olive, 11th/Grand, 11th/Hope, 11th/Flower, 11th/Figueroa, Olympic/Figueroa, 9th/Figueroa, 8th/Figueroa, 7th/Figueroa, 7th/Flower, 7th/Hope, 7th/Grand, 7th/Olive, 7th/Hill, 6th/Hill, 5th/Hill, 4th/Hill, 3rd/Hill, and 2nd/Hill. The intersection evaluations were performed for the Base Condition and three improvement scenarios.

The Base Condition consisted of running Synchro at the 34 intersections with the streetcar alignment in place using the latest available traffic volumes at each intersection, the latest intersection lane configurations and associated restriping from the development and streetscape projects that have been completed, and the latest traffic signal timing information along Broadway due to the implementation of the streetscape project. All of the latest available information was collected and provided by LADOT.

Scenario 1 consisted of reviewing the results of the field observations and reviewing the streetcar movement delay results from the Base Condition to identify potential physical and operational intersection improvements that would improve the run time estimate. The improvements proposed to improve the streetcar delay are presented in the Assumptions section.

Scenario 2 builds off the improvements proposed in Scenario 1 and would also add a second southbound lane on Broadway from 2nd to 11th Streets. As a result of having two southbound lanes on Broadway, the curb lane includes buses and the streetcar tracks and is designated as a "Transit Only" lane and the second lane will accommodate all other mixed flow vehicles. However, it should be noted that mixed flow vehicles would be permitted to weave across the "Transit Only" lane and the streetcar tracks to access the southbound right turn pocket lanes along Broadway at 2nd, 3rd, 5th, 7th, 8th Streets, and Olympic Boulevard.

Scenario 3 builds off the improvements proposed in Scenario 1 and would designate the single southbound lane on Broadway from 2nd to 11th Streets as a "Transit Only" lane to accommodate buses and the streetcar tracks. All mixed flow vehicles currently traveling in the southbound direction of

Broadway would be diverted to adjacent roadways such as Hill and Spring Streets. Local access to businesses along the southbound direction of Broadway would travel along Hill and Spring Streets and circle back onto the northbound direction of Broadway to access their final destination. Except for transit vehicles, southbound right turn movements at 2nd, 3rd, 5th, 7th, 8th Streets, and Olympic Boulevard would be prohibited. It is assumed that 25 percent of the mixed flow vehicles along southbound Broadway would be local access trips and that 75 percent of the mixed flow vehicles are through trips. The distribution of the southbound through trips between Hill and Spring Streets used the same percentages that were presented in the Broadway Streetscape Plan Traffic Study dated November 2010.

Streetcar Run Time Estimates

To determine estimated streetcar run times, a run time analysis was completed along the corridor in September 2015, replicating the project alignment. The process started with a floating car travel time analysis to determine typical PM peak travel time and delay along the corridor. This analysis was performed to serve as a base to calibrate both an existing Base Condition Synchro network to model traffic signal delays and an existing streetcar run time model to determine streetcar performance if no improvements were made.

The streetcar run time models are based on station to station run times, dwell times and signalized intersection delays for the streetcar movement. The assumptions for each of these parameters are presented in the next section of this document.

Based on the initial Synchro delays, a Base Condition scenario was developed to show projected run times assuming no improvements were made.

Building on the Base Condition, Scenario 1 was developed with minimal improvements including optimization of existing signal timing splits. No Transit Signal Priority (TSP) timings were assumed in this analysis. There were no lane use changes made for Scenario 1. The run times were based on a revised Synchro output which reflected the adjusted signal timings, the addition of a protected right turn phase, where applicable, and the proposed addition of a right turn pocket lane at two intersection locations.

Scenario 2 was developed based on the signal time improvements in Scenario 1 and lane geometry changes along Broadway. Two southbound travel lanes are provided in this scenario from the one southbound lane currently available.

Scenario 3 converts the one southbound lane on Broadway to a transit only lane, including the streetcar. Scenario 3 also assumed the signal timing improvements made for Scenario 1.

Scenario 4 incorporates the incremental signal timing improvements included in Scenario 1, but consolidates the number of streetcar station stops from 25 to 16 and spaces them about every 1/4 mile from every 1/8 mile. The stations included in Scenario 4 are: 2nd/Grand, 2nd/Broadway, 4th/Broadway, 6th/Broadway, 8th/Broadway, Olympic/Broadway, 11th/Grand, 11th/Figueroa, 9th/Figueroa, 7th/Figueroa, 7th/Grand, 7th/Hill, 5th/Hill, Angel's Flight/Grand Central Market, 2nd/Hill, and 2nd/Grand.

Results of the run time analyses are presented later on in the technical memorandum.

Assumptions

The following assumptions were made for the Small Starts Speed Improvement Analysis for each of the intersection evaluations and the run time estimates.

<u>Intersection Evaluations</u>

- Existing (2015) intersection lane configurations were collected and verified by field observations;
- The analysis was based on existing 2014/2015 traffic counts provided by LADOT;
- Available traffic counts that are older than 2014/2015 were used and grown by an annual growth rate of 0.5% per year to reflect existing conditions (this ambient growth rate was used in the EIR traffic study and approved by LADOT);
- Existing signal timing was used. LADOT provided the latest signal timing changes along Broadway that were implemented due to the Streetscape Demonstration Project;
- Existing signal cycle lengths were maintained. The general PM peak hour cycle length is 90 seconds for the analyzed intersections. All current signal off-set parameters remained the same in the analysis;
- On one lane roadways, the bus blockage factor in the Synchro software was utilized to account for potential delays due to near side stops and the anticipated 20-second dwell time for passengers to board and alight;
- Extended yellow clearance times used in the EIR traffic study to reflect the potential for a streetcar to arrive at the intersection near the end of the green time and needing an extra clearance interval to safely clear the intersection were maintained;
- The traffic analysis was based on the streetcar characteristics that were presented and approved in the EIR traffic study. This included a 7-minute headway streetcar operation during the peak hours (9 streetcars per hour);
- Proposed improvements to reduce the streetcar delay consisted of:
  - Redistributing the green time within the existing signal cycle length to provide more green to the streetcar movement/direction. The amount of green time ranged from 5 to 15 seconds and depended on the needs at each intersection;
  - Adding a right turn only pocket lane. This was proposed at Broadway/11th Street and at Hill/6th Street;
  - Providing a protected right turn arrow to clear the right turn queue before or after the crossing of pedestrians. This was proposed at Broadway/3rd Street, Broadway/5th Street, Broadway/8th Street, and Figueroa/7th Street;
  - Extending the existing eastbound right turn lane storage length at Flower/7th Street to accommodate 6 to 7 turning vehicles in order to minimize queue spillover onto the eastbound 7th Street through movement.

The assumed physical and operational intersection improvements are intended to reduce the streetcar delay. Ongoing coordination between City of Los Angeles and Metro will be required for implementing these improvements

Streetcar Run Time Estimates

The estimated vehicle run time models are based on typical streetcar acceleration/deceleration rates of 2.5 mph per second and average dwell times of 20 seconds at each stop. The signal delay times are based on the Synchro output of total delay for the streetcar movement at each of the signalized intersections along the streetcar alignment within the study area. The total delay at signalized exclusive pedestrian crossings was assumed to be 10 seconds per signal.

The run time analysis does not include any layover times, and a total cycle time was not analyzed for the purpose of this estimate. It is assumed that the vehicle layover will occur at the 2nd/Grand station.

Station locations, distances and curve data at intersections were based on the previous concept plans that are being used as the basis of the Environmental Documents. The maximum allowable streetcar speed was assumed to be the same as the posted speed limits.

Findings

The results and findings of the intersection evaluations and streetcar run time estimates for the Base Condition and various improvement scenarios are presented in the following sections.

Intersection Evaluations

The total delay for the streetcar movement was reported at each of the 34 intersections for each of the analysis scenarios. The attached summary table presents the PM peak hour delay for each scenario that was evaluated along with the improvements proposed. As shown from the results, the delays in Scenario 1 improve from the Base Condition due to the improvements proposed at thirteen intersection locations. In addition, improvements are proposed at three intersection locations based on the field observations. Scenario 2 continues to improve the delay, from Scenario 1, at eight intersection locations along Broadway. Scenario 3 continues to improve the delay, from Scenario 2, at eight intersection locations along Broadway. The delay numbers that improve from the previous scenario are shown in bold in the summary table. In addition, it should be noted that Scenario 3, which consists of the "Transit Only" lane along southbound Broadway, results in six (6) intersections being significantly impacted when the overall intersection delay is compared to that of the Base Condition. The six significantly impacted intersection locations are at 1st/Hill, 3rd/Hill, 7th/Hill, Olympic/Hill, Olympic/Broadway, and

PM Peak Hour Delay for the Movements Along the Streetcar Alignment – Summary Table

PM Peak Hour Delay per Vehicle (Seconds per Vehicle)						
Intersection	**Movement**	**Base Condition**	**Scenario 1**	**Scenario 2**	**Scenario 3**	**Improvements Proposed For Scenarios 1, 2, and 3**
Grand Ave / 1st St	NB Right	11	11	11	11	(Note that EIR assumes new protected streetcar phase for NB right turn from median)
Grand Ave / 1st St	WB Left	74	**49**	49	49	Redistribute the green time within the existing cycle length
Olive St / 1st St	EB Thru	32	32	32	32

Scenario 1 = The Base Condition with the Proposed Intersection/Signal Timing Improvements

Scenario 2 = The Proposed Intersection/Signal Timing Improvements from Scenario 1 plus Two SB Lanes (1 MF & 1 Transit Only) on Broadway from 2nd to 11th Streets

Scenario 3 = The Proposed Intersection/Signal Timing Improvements from Scenario 1 (where applicable) plus One SB Transit Only Lane on Broadway from 2nd to 11th Streets

Olympic/Main. These locations show significant impacts from the Base Condition due to the fact that mixed flow vehicles were diverted to the adjacent roadways, such as Hill Street and Spring/Main Streets. The Synchro delay worksheets, at each intersection location, for the Base Condition and all three scenarios are presented in Attachment 1. It should be noted that Scenarios 2 and 3, which include a "Transit Only" lane along the southbound direction of Broadway, do not show a greater reduction in delay than what would be anticipated over Scenario 1 because the overall intersection cycle length and green times are allocated so that all traffic volumes and movements, as well as pedestrian movements, are accommodated adequately to clear the intersection and minimize queuing and prevent potential spillback to adjacent upstream intersections.

Streetcar Run Time Estimates

The results of the streetcar run time analyses for all scenarios, including the Base Condition are shown in the table below. The detailed run time worksheets are presented in Attachment 2.

Streetcar Run Time Analysis Results

Scenario	Run Time (hr:min:sec)	Delay Time (hr:min:sec)	Dwell Time (hr:min:sec)	Total Time (hr:min:sec)	Average Speed (mph)
Base Case Synchro Output	00:13:11	00:24:59	00:07:40	00:45:50	5.0
Scenario 1 Synchro Output - Base with Improvements	00:13:11	00:17:42	00:07:40	00:38:33	5.9
Scenario 2 Synchro Output - Two SB Broadway Lanes	00:13:11	00:17:08	00:07:40	00:37:59	6.0
Scenario 3 Synchro Output - Broadway Transit Only Lane	00:13:11	00:16:12	00:07:40	00:37:03	6.1
Scenario 4 Synchro Output - Base Case with Improvements and 16 Stops	00:11:36	00:17:42	00:04:40	00:33:58	6.7

As shown in the table, Scenario 4, with the 16 station stops, provides the fastest streetcar run time at just under 34 minutes. With the full 25 station stops, Scenario 3 provides the fastest run times at just over 37 minutes.

Conclusions

Redistributing 5 to 15 seconds of green time at 11 intersections, providing a protected right turn phase at 4 intersections, extending the right turn lane at one location, and providing new right turn lanes at two locations (Scenario 1), saves seven minutes of run time, getting us within 3.5 minutes of the 35 minute run time goal.

Adding a second lane southbound on Broadway with one of the two lanes being transit-only (Scenario 2) saves 34 seconds of run time compared to Scenario 1.

Converting the one southbound lane on Broadway to transit-only (Scenario 3) saves 90 seconds of run time compared to Scenario 1, but causes significant traffic impacts at six intersection locations.

Reducing the number of streetcar station stops from 25 to 16 by increasing the spacing from about 1/8 mile to 1/4 mile (Scenario 4), saves 4.5 minutes in run time compared to Scenario 1. Combined with the proposed Scenario 1 modifications, this would achieve the goal of a run time of less than 35 minutes. A STOPS ridership estimate was performed by Metro with the reduced number of streetcar station stops. The result was a reduction of 300 boardings per day, from 5,700 riders to 5,400 riders. The STOPS model results are presented in Attachment 3.

						Avg. Speed =	6.7 mph	
						Avg. Station Spacing=	0.25 miles	

NOTES:
1. Stationing, distances and horizontal curve radii based on LA Streetcar Routes for Final Screening.pdf
2. Assumed maximum allowable speed on mixed traffic roadways = 35 mph.
3. Intersection delay based on Synchro output.
4. Average ped. crossing delay = 10 seconds.
5. Acceleration & deceleration rates based on Skoda 10T normal performance (2.5 mphps).
6. Average dwell time = 20 sec. surface stations.

ATTACHMENT 3 – STOPS MODEL RESULTS

Run #	Description	Speed	Project Ridership	New Transit Trips
15	7th with Spur	6.5	6,358	3,464
25	7th with Spur	5.5	5,260	2,743
17	7th with Spur	4.5	4,339	2,135
22	7th Without Spur	4.5	3,077	1,248
23	9th with Spur	4.5	4,224	2,179
24	9th without Spur	4.5	3,019	1,317
26	7th with Spur Less Stops	6.5	5,368	3,188

Metro

L.A. Downtown Streetcar Project

7th Street With Spur with Less Stops (6.5 Miles / Hour)

Appendix M
Energy Calculations

LA Streetcar Energy Calculations (revised 5-25-16)

VMT Reduced (daily)

Alt.	2015	2020	2040
2	6,813	7,172	8,606
3	5,464	5,724	6,767
4	6,694	7,055	8,499
5	4,873	5,123	6,123

	2015	2020	2040
MPG [1]	21.26	24.35	35.61

Gallons Reduced (daily)

Alt.	2015	2020	2040
2	320	295	242
3	257	235	190
4	315	290	239
5	229	210	172

Gallons Reduced (annually @ 365 days/ year)

Alt.	2015	2020	2040
2	116,968	107,506	88,211
3	93,808	85,801	69,361
4	114,925	105,753	87,114
5	83,662	76,792	62,760

Annual BTUs Reduced (@120,556 BTU/gal) [2]

Alt.	2015	2020	2040
2	-14,101,224,375	-12,960,537,400	-10,634,352,756
3	-11,309,128,135	-10,343,853,329	-8,361,917,860
4	-13,854,923,817	-12,749,106,435	-10,502,133,869
5	-10,085,904,357	-9,257,784,871	-7,566,133,154

Footnotes: [1] Fuel economy factors used = Light Duty Auto (LDA) & Light Duty Truck (LDT). Taken from *EMFAC2014 (v1.0.7) Emissions Inventory; Los Angeles County; EMFAC2011 Categories.* [2] Energy content of fuel calculated from U.S. Energy Information Administration (EIA); carbon dioxide emissions coefficients, https://www.eia.gov/environment/emissions/co2_vol_mass.cfm. Annual BTUs Reduced (in MMBtu)

Alt.	2015	2020	2040
2	-14,101	-12,961	-10,634
3	-11,309	-10,344	-8,362
4	-13,855	-12,749	-10,502
5	-10,086	-9,258	-7,566

Energy Figures for Table 3.4-3 (Annual MMBtu)

		Build Alts 2 and 4	Build Alts 3 and 5
MSF Energy Consumption	Electricity	740	
	Natural Gas	339	
	Worker commuting	2,379	
	Subtotal	3,458	
Streetcar Operation	Electricity	10,666	10,058
Subtotal - MSF + Streetcar Operations		14,124	13,516

Energy Savings from VMT Reductions			
	2015	2020	2040
Alt. 2	-14,101	-12,961	-10,634
Alt. 3	-11,309	-10,344	-8,362
Alt. 4	-13,855	-12,749	-10,502
Alt. 5	-10,086	-9,258	-7,566

Net Energy Consumption (MMBtu)			
	2015	2020	2040
Alt. 2	23	1,163	3,490
Alt. 3	2,207	3,172	5,154
Alt. 4	269	1,375	3,622
Alt. 5	3,430	4,258	5,950

Input Assumptions				
1 kWh =	3412.141633	BTU		
	120,556	BTU/gallon	419,611	annual miles per CalEEMod
			19,737.11	2015 gallons
Streetcar electricity	60,115	kWh/week		
	3,125,980	kWh/year
