| 16. Abstract<br><p>The objectives of this study were to classify the energy used by the Washington Metrorail into its primary end uses, and to identify those energy conservation strategies which have the highest potential for reducing energy cost. The effort involved analyzing present energy costs, developing cost-effective energy conservation strategies, simulating the energy cost savings associated with these strategies, recommending the appropriate strategies for implementation and outlining a program for executing the recommendations.</p> <p>The study is the first time that the Energy Management Model, developed for the transit industry by the Rail Systems Center at Carnegie-Mellon University, was comprehensively applied to a rapid transit property. The application was verified by comparing the simulated results to actual data. For all practical purposes, the simulated results agree to within 3% of the actual energy consumption.</p> <p>Five energy conservation strategies were recommended for implementation based on high benefit and low cost. These are: coasting, passenger load factor improvement, planned catch-up operation, regeneration of braking energy and passenger station lighting improvement. All of these strategies have payback periods less than three years.</p> |  |  |                                      |

## 9. APPENDIX

### 9.1. PASSENGER LOAD FACTOR ESTIMATES

The passenger load factor used in this report is based on crush loaded vehicles, since it is used in the TPS, to provide an estimate of the weight of the train. It is defined as the percentage ratio of the number of passengers to the number of crush load spaces between any two adjacent stations. A 0% load factor implies an empty train whose cars weigh 36 tons, while a 100% load factor represents a crush loaded train whose cars weigh 52.5 tons, and carry 220 150-pound passengers, each. The weight of 52.5 tons is the maximum car weight.

The passenger load factors between stations were developed using origin-destination data from the spring 1980 Metrorail Survey (Phase IV) and the 1980 operating timetable.

The origin-destination data consisted of station-to-station passenger counts on a weekday, during the four revenue service operating periods: AM Peak(6:00-9:30A), Midday (9:30A-3:00P), PM Peak (3:00P-6:30P), and Evening (6:30P-12:00A). No detail was available on the variation within these four periods. No data were available for Saturday and Sunday operation.

Passenger spaces were computed using the 1980 timetable. The results are shown in the table below:

CRUSH LOAD PASSENGER SPACES IN EACH DIRECTION

|         | <u>Red Line</u> | <u>Blue Line</u> | <u>Orange Line</u> | <u>Blue/Orange Line</u> |
|---------|-----------------|------------------|--------------------|-------------------------|
| AM PEAK | 57860           | 46580            | 46580              | 87060                   |
| MIDDAY  | 47540           | 41050            | 41050              | 77570                   |
| PM PEAK | 56660           | 48620            | 48620              | 91520                   |
| EVENING | 44660           | 35810            | 35810              | 68370                   |

On the Red Line, the link volumes between each station were divided by the number of crush load passenger spaces to determine the passenger load factors. To obtain the passenger load factors on the Orange and Blue Lines, the link volumes were divided by:

- Blue/Orange spaces for stations between Rosslyn and Stadium Armory,
- Blue spaces for stations between National Airport and Rosslyn,
- Orange spaces for stations between Ballston and Rosslyn, and between Stadium Armory and New Carrollton.

All of the load factors are summarized in the Figures 9.1-1 to 9.1-24.

## 9.2. ESTIMATE OF METRORAIL TRAIN RESISTANCE

The purpose of this exercise is to determine the coefficients of a Davis type formula which fits the coefficients of an empirical formula obtained from coast down measurements of Metro trains.

The Davis type formula used for the TPS has the form:

$$T_R = 1.3 + (29n/W) + fv + (0.0024 + 0.00034(c-1))/W \times Av^2$$

where:

A = train cross sectional area (sq. ft.),

C = number of cars/train,

f = flange coefficient,

n = number of axles per train,

$T_R$  = train resistance (lbs/ton),

v = speed (MPH),

W = weight of train (tons).

Train resistance coast down tests were conducted at the U.S. Department of Transportation, Transportation Test Center in Pueblo, Colorado, sometime during the period September 1976 to August 1977.<sup>13</sup> The results were fitted to the formula for the deceleration of the car of:

$$a = a_0 + a_1 v + a_2 v^2$$

where  $a_0$ ,  $a_1$  and  $a_2$ , upon regression analysis, were found to have the following values:

$$a_0 = .041,$$

$$a_1 = .00071,$$

$$a_2 = .000024.$$

---

<sup>13</sup> WMATA Rapid Transit Vehicle Engineering Tests, K.J. Simmonds and F. H. Henderson, Final Report, May 1979, Report No. UMTA-MA-06-0025-79-14.

The consist upon which these data were based was a two-car train with each car weighing 96,000 lbs (AW2).

Since for coast down tests we can relate the deceleration to the train resistance by the relation  $T_R = 100 \times a$ , which includes the effect of train rotational weight, equating the like coefficients of the powers of  $v$  yields the relations:

$$a_0 = .041 = (1.3 + (29.8/96)) / 100 = .037$$

$$a_1 = .00071 = f / 100 \text{ or } f = .071$$

$$a_2 = .000024 = ((.0024 + .0034)/(96 \times 100)) A \text{ or } A = 85.$$

Thus, if the flange coefficient,  $f$ , is taken as .071 and the effective cross sectional area as  $85 \text{ ft}^2$ , the train resistance of the cars can be approximated with a Davis type formula.

These numbers were used as the basis of the train resistance for the TPS.

### 9.3. SYSTEM FLOW CHART FOR THE ANALYSIS OF PEPCO TAPE

We received the tape, from PEPCO, which contains the data as given in the PEPCO account. The data had 15 minute pulses for each PEPCO meter, for the year 1980. The data was converted into Fortran readable form, using RU0A09.FOR. We created, using METCON.FOR, one file for each meter containing data from February 1, 1980, to October 15, 1980, for 15 minute intervals by combining meter readings for all the three phases. These files were then used for further statistical analysis, namely:

- (i) Using COMMET.FOR, we combined different files to get five PEPCO meter files,
- (ii) Using STAT.FOR, we found summary statistics which have provided mean, standard deviation for 15 minute intervals, one hour intervals, and for some specified periods of weekdays, Saturdays and Sundays.
- (iii) Using (A), we created plots carrying summary statistics. This provided, through bar charts, information on mean, standard deviation and maximum of power demand.
- (iv) Using (B), we did regression analyses of Power vs. Car-Miles/Hour and Degree-Days for revenue operating and non-operating periods.

(v) Using (C), we created energy consumption HISTOGRAMS on each time period for various meters.

The System's flow chart is shown in Figure 9.3-1.

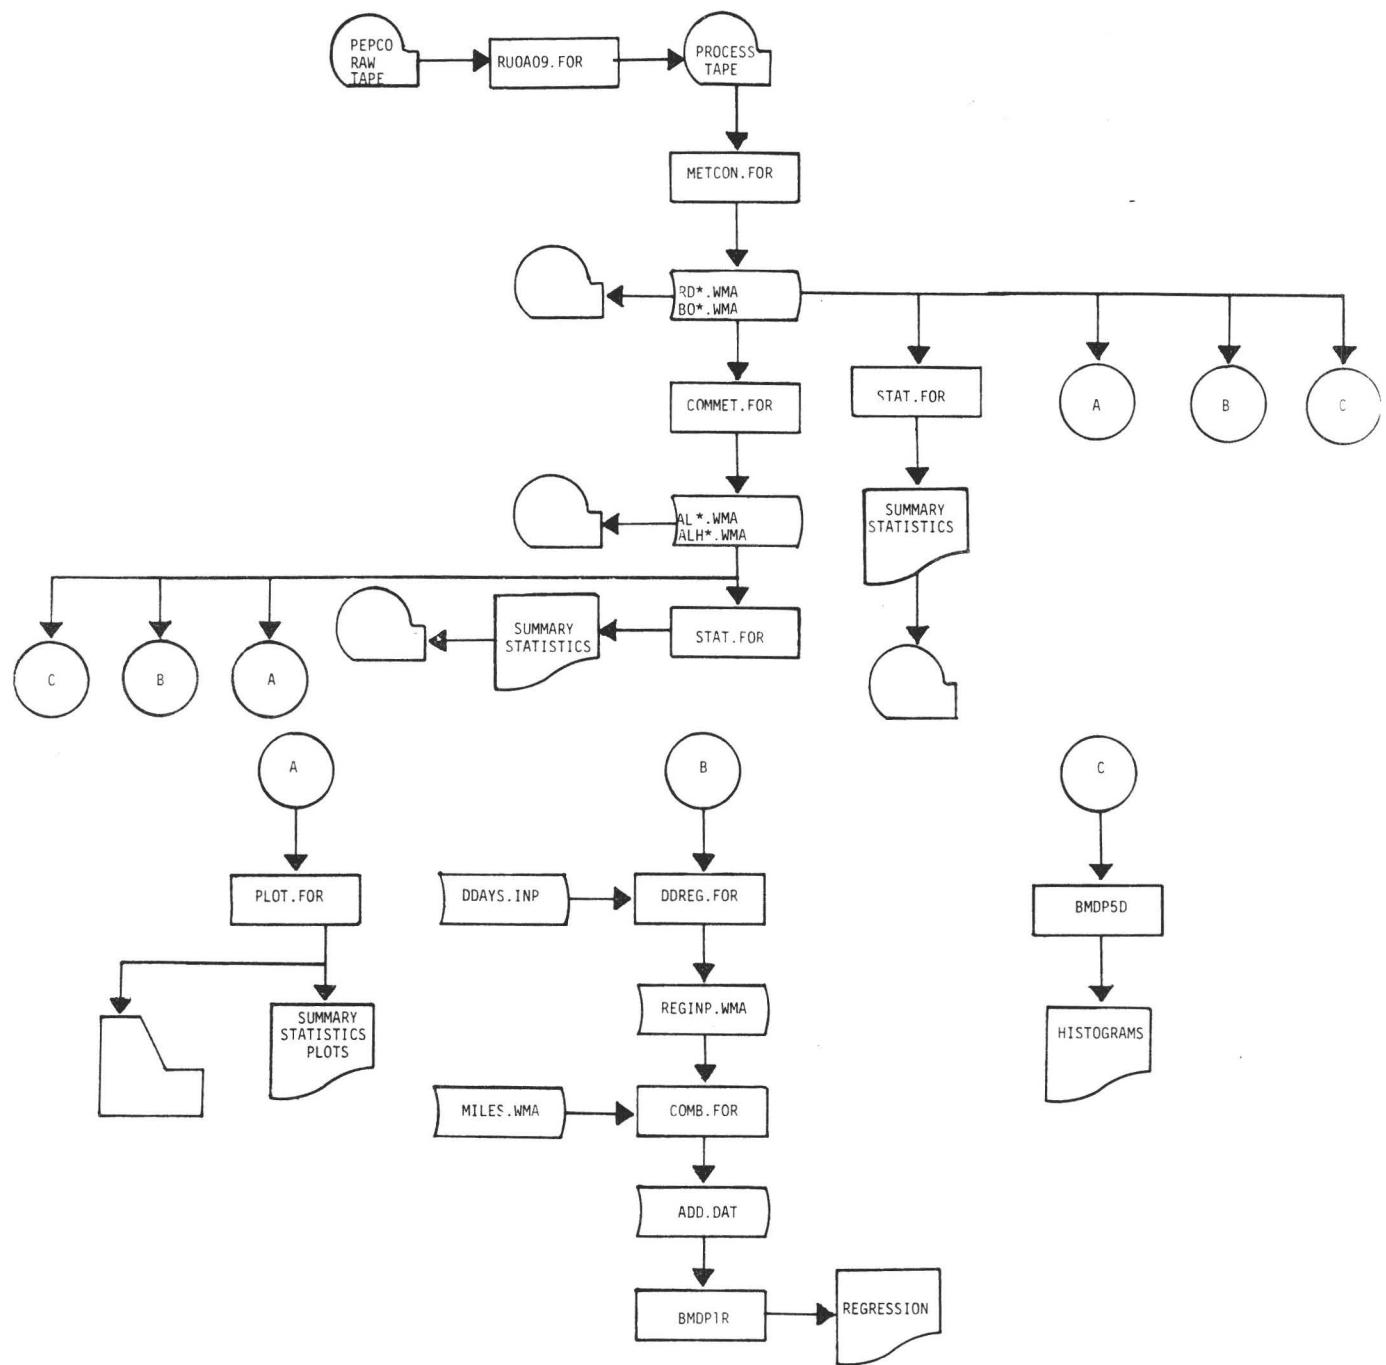

FIGURE 9.3-1 SYSTEM FLOW CHART

#### 9.4. REGRESSION ANALYSIS DETAIL INCLUDING THEORY AND RESULTS

##### Regression Technique

A package BMDP1R, one of the computer packages of BMDP<sup>2</sup> series, is used that estimates a multiple linear regression relating a dependent variable (in our case POWER) to several independent variables (e.g., degree-day and car-mile/hour in our case).

Let  $y$  represent the value of the dependent variable, and  $x_1, x_2 \dots x_n$  the values of the independent variables, then the proposed relationship is:

$$y = a + \beta_1 x_1 + \beta_2 x_2 + \dots \beta_n x_n + \text{error}$$

The package estimates by least squares the coefficients  $a, \beta_1, \beta_2 \dots \beta_n$ , that is, it finds  $a, b_1, b_2 \dots b_n$  (estimates of  $a, \beta_1, \beta_2 \dots \beta_n$ ) that minimize

$$\sum (y - a - b_1 x_1 - b_2 x_2 - \dots - b_n x_n)^2$$

Here the summation is over the cases used in the analysis. The predicted value  $\hat{y}$  for each case is:

$$\hat{y} = a + b_1 x_1 + b_2 x_2 + \dots + b_n x_n$$

The residual for each case is  $(y - \hat{y})$ . Thus, a multiple linear regression equation can be written as:

$$E(y_j - \bar{y}) = \beta_1(x_{1j} - \bar{x}_1) + \dots + \beta_n(x_{nj} - \bar{x}_n) \\ j = 1, 2 \dots N \text{ (number of cases)}$$

In matrix notation:

$$E(\underline{Y}^1) = \underline{X}^1 \underline{B}^1$$

where:

$\underline{Y} = (y_j - \bar{y})$  is a row vector of length  $N$ ,

$\underline{X} = (x_{ij} - \bar{x}_i)$  is a  $n \times N$  matrix,

$\underline{B} = (\beta_i)$  is a row vector of length  $n$ ,

$\underline{X}^1$  and  $\underline{Y}^1$  are the transpose matrices of  $\underline{X}$  and  $\underline{Y}$ , respectively.

<sup>2</sup>BMDP (Biomedical Computer Programs) has been developed by Health Sciences Computing Facility of the University of California, Los Angeles.

The least square estimate  $\hat{b}$  of  $\beta$  is  $\hat{b}^1 = (\tilde{X}\tilde{X}^1)^{-1}\tilde{X}\tilde{Y}^1$ .

### Coefficients and Measures of Fit

The statistical descriptive package provides as output:

a. **Regression Coefficients:**

A summary table for the regression is printed. It contains:

the coefficients  $b_i$ ,

the standard error of the coefficient  $S(b_i)$ ,

the standardized regression coefficient  $b_i S_x / S_y$ .

t test for the coefficient  $b_i / S(b_i)$  and the associated two tailed value.

b. **Univariate Statistics:**

Univariate statistics computed for each variable are:

mean,

standard deviation,

coefficient of variation,

minimum observed value,

maximum observed value.

c. **Correlation Matrix:**

A correlation matrix of the dependent and independent variables is calculated which is used to test the multicollinearity among variables (an assumption for regression).

The correlation of the dependent variable with the predicted value R is estimated as well as the multiple:

$$R^2: \left( 1 - \sum (y_j - \hat{y}_j)^2 / \sum (y_j - \bar{y})^2 \right)$$

standard error of estimate:

$$\sqrt{\sum (y_j - \hat{y}_j)^2 / (N - n)}$$

**d. Analysis of Variance:**

The analysis of variance table for the regression is printed. It contains:

the regression sum of squares:  $\sum(\hat{y}_j - \bar{y})^2$

the residual sum of squares:  $\sum(y_j - \hat{y}_j)^2$

an F ratio that tests the significance of the regression.

**e. Tests for Significance:**

The package provides three different tests for significance, namely,

$R^2$ ,

t test,

F test.

The  $R^2$  tests the significance of overall regression equation (value of  $R^2$  greater than 0.5 is supposed to be significant for cases having two independent variables).

The t test is used to test the significance of individual coefficients  $b_i$ . The summary table contains the t test for the coefficient  $b_i/S(b_i)$  and the corresponding two tail probability value. Again, a t value with 95% confidence level (approximately 2.2 for most of the cases) has been chosen to test the significance of independent variable in the given regression equation.

An F value at 95% level of confidence (3.1 for two independent variable cases, and 3.9 for one independent variable case) is used to ascertain the significance.

**Sources of Error (Notes)**

1. In order to ensure that erroneous stray points do not affect the equation estimation process, all observations (considering car-miles only) having large error (beyond 3 times the standard deviation) are excluded from the analysis. (Ref.: Chauvert, Spherical and Practical Astronomy, vol. II, p. 558, Lippincott, Philadelphia)

2. Differences in intercepts and spurious correlation:

Let us take a hypothetical situation as given in Figure 1. It is assumed here that the background power (intercept in power =  $a + b_1$  car-miles/hr +  $b_2$  D-Day) is different for the three types of groups of days - Sundays, Saturdays, and weekdays. In case of meters with low background (e.g., MC3, MD4, and MD7), if we run a regression, we may end up getting a least square fit of Type 4, resulting in a negative background. (In actual regression fits, the slope of the regression will be closer to that of (1), (2) and (3) because:

1. weekdays are more, and therefore entail higher weightage;
2. in the figure we have used extreme differences only to show a degenerate case.)

Given (4), there is no way of computing (1), (2) and (3). While the slope differences are likely to be nominal, the intercept differences in some cases turned out to be fairly large. This is due to the fact that car-miles account for a fairly large component in traction meters. For all meters considered together, the differences even out and intercepts become more accurate (due to law of large numbers). Due to this spurious fitting during operating hours, it is preferable to ignore intercepts for the individual meters in the regressions and concentrate on the intercept from all the meters combined only. Again, since during non revenue time, car-mile effect is very small as compared to revenue time, the intercept in the linear regression equation of Power vs. Degree-Day will be the true background.

The following tables in subsections 9.4.1 through 9.4.8 contain the regression results for the Red and Blue/Orange traction meters as well as support meters during revenue operating periods and non-operating periods.

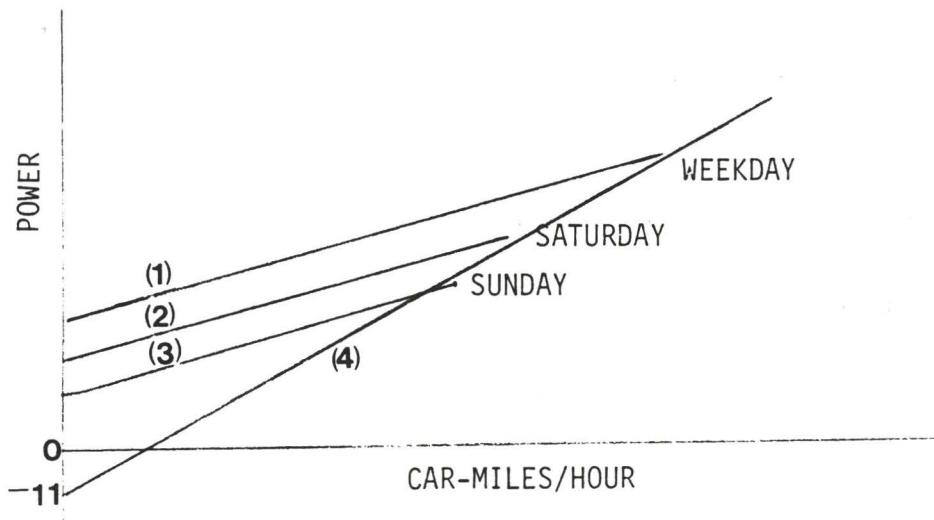

FIGURE 1: A DEGENERATE CASE OF BLUE/ORANGE MC3 METER

### 9.8. DEVELOPMENT OF ESCALATOR FORMULA

All of the escalators used in Metrorail passenger stations are manufactured by Westinghouse Electric Corporation under the registered trademark name of Moduline 100.

Data were obtained from Westinghouse Elevator Division<sup>15</sup> on tests which were conducted on the power consumption of these escalators. These tests were conducted on an escalator which has a height rise of 17 ft, a speed of 90 ft/min and a width of 32 inches. The results are shown in Figure 9.8-1.

For loads which would be experienced by most of the escalators during most of the Metrorail operations, the power density of the modular escalators is linearly related to the people density,

$$PD = 0.59pd + 0.11$$

where PD is the Power Density in KW/ft of rise, pd is the people density in persons/ft of rise.

With the assumption of linearity, it can be shown that the power developed by all of the escalators is:

$$P = 0.11R_T + [F_{+} - |F_{-}|]R / 4580$$

where  $F_{+(-)}$  is the people flow rate on up (down) escalators,  $R_T$  is the sum over all of the escalator rises and R is the average escalator rise (assumed escalator speed is 90ft/min).

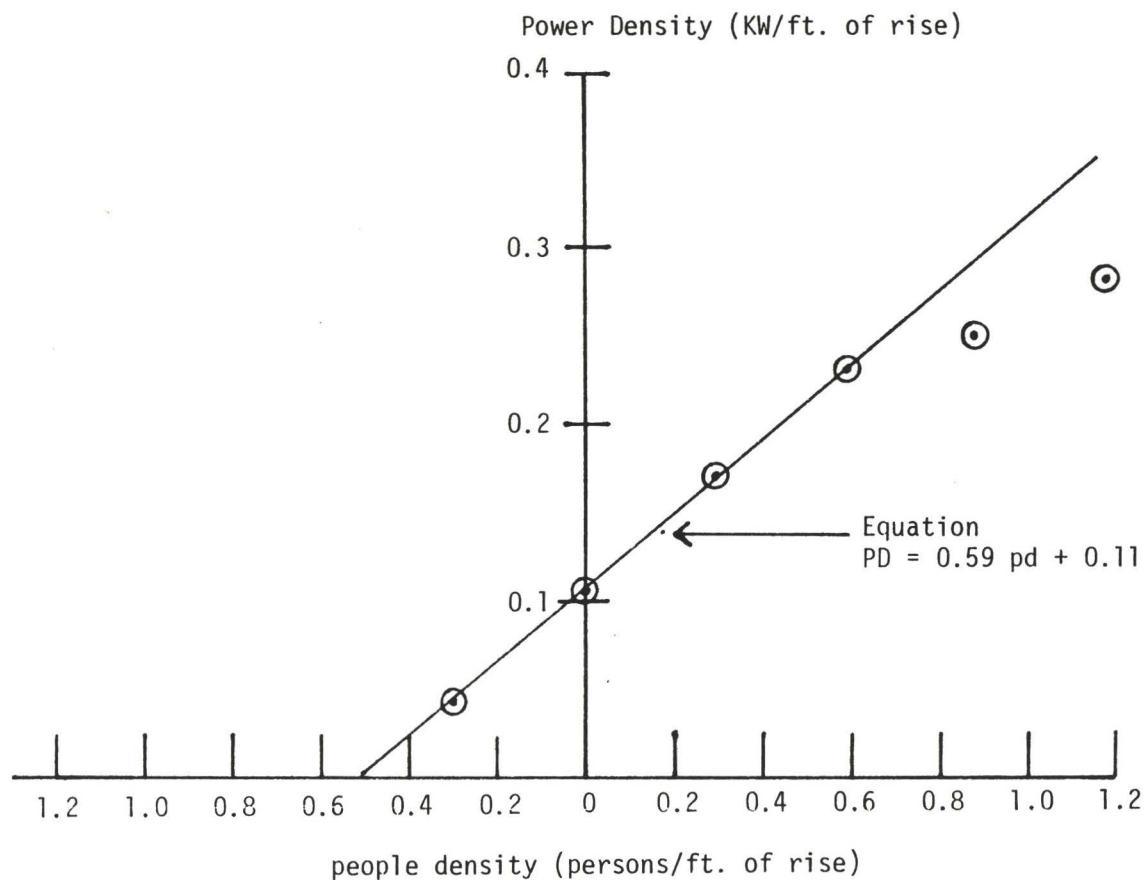

If we assume that as many people enter a station as leave it over certain operating periods (AM and PM Peak, Midday, Evening, etc.) then the second term in the above expression is zero and the average power is:

$$P = 0.11R_T$$

This resulting formula was used in all of the escalator power estimates.

---
